Abstract

We consider distributed statistical optimization and inference in the presence of heterogeneity among distributed data blocks. A weighted distributed estimator is proposed to improve the statistical efficiency of the standard “split-and-conquer” estimator for the common parameter shared by all the data blocks. The weighted distributed estimator is at least as efficient as the would-be full sample and the generalized method of moment estimators with the latter two estimators requiring full data access. A bias reduction is formulated for the weighted distributed estimator to accommodate much larger numbers of data blocks (relaxing the constraint from $K = o(N^{1/2})$ to $K = o(N^{2/3})$, where $K$ is the number of blocks and $N$ is the total sample size) than the existing methods without sacrificing the statistical efficiency at the same time. The mean squared error bounds, the asymptotic distributions, and the corresponding statistical inference procedures of the weighted distributed and the debiased estimators are derived, which show an advantageous performance of the debiased weighted estimators when the number of data blocks is large.

Keywords: bias correction; distributed inference; heterogeneity; split-and-conquer method; weighted estimation.

1. Introduction

Modern big data have brought new challenges to statistical inference. One such challenge is that despite the sheer volume of the data, full communication among the data points may not be possible due to either the cost of data communication or the privacy concern. The distributed or the “split-and-conquer” method has been proposed to divide the full data sample into smaller size data blocks to avoid data communication. The split-and-conquer estimator is also suited to situations where the data are naturally divided into data blocks and data communication among the data blocks are prohibited due to privacy concern. The “split-and-conquer” estimation has been considered in Lin and Xi (2010) for the U-statistics, Zhang et al. (2013) for the statistical optimization, Chen and Xie (2014) for the generalized linear models, Volgushev et al. (2017) and Chen et al. (2019) for the quantile regression, Battey et al. (2018) for high dimensional testing and estimation, and Chen and Peng (2021) for asymptotic symmetric statistics (Lai and Wang, 1993). Bootstrap resampling-based methods had been introduced to facilitate statistical inference. Kleiner et al. (2011) proposed the bag-of-little bootstrap (BLB) method for the plug-in estimators by making up economically the full
sample for the distributed inference. Sengupta et al. (2015) suggested a sub-sampled double bootstrap method designed to improve the computational efficiency of the BLB. Chen and Peng (2021) proposed the distributed and the pseudo-distributed bootstrap methods with the former conducting the resampling within each data block while the latter directly resampling the distributed statistics.

Privacy has been a major concern in big data applications where people are naturally reluctant to share the raw data to form a pool of big data as practised in the traditional full sample estimation. However, the data holders may like to contribute summary statistics without having to give away the full data information. Federated Learning or the distributed inference with a central host has been proposed to accommodate such reality (McMahan et al., 2017; Yang et al., 2019; Li et al., 2020; Kairouz et al., 2021), where summary statistics of the data blocks or the gradients of the objective functions associated with the private data blocks are submitted to a central host for forming aggregated estimation or computation.

Homogeneous distribution among the data blocks is assumed in the majority of the statistical distributed inference studies with a few exceptions (Zhao et al., 2014; Duan et al. 2021). Federated Learning, on the other hand, was introduced to mitigate challenges arising from classical distributed optimization. In particular, heterogeneous or non-IID distributed data across different data blocks is one of the defining characteristics in the Federated Learning (Li et al., 2020; Kairouz et al., 2021). Indeed, it is natural to expect the existence of heterogeneity, especially for data stored in different locations or generated by different stochastic mechanisms, for instance, mobile phones of different users. But few works have focused on the asymptotic statistical properties of the estimator, especially in a heterogeneous setting.

**Main Contributions.** This paper considers distributed statistical inference under heterogeneous distributions among the data blocks, where there is a common parameter shared by the distributions of the data blocks and data-block-specific heterogeneous parameters. It is noted that Duan et al. (2021) also considered a heterogeneous setting but under a fully parametric framework. Specifically, the main contributions of this paper are as follows:

- Our study reveals that in the presence of heterogeneity the full sample estimator of the common parameter obtained by requiring full data access, can be less efficient than the split-and-conquer estimator. It is found that this phenomenon disappears if the objective function of the statistical optimization satisfies a generalized second-order Bartlett’s identity.

- We propose a weighted distributed (WD) estimator, which is asymptotically at least as efficient as the full sample and the split-and-conquer estimators when the number of data blocks $K = o(N^{1/2})$, where $K$ is the number of data blocks and $N$ is the total sample size. The mean squared error bound and the asymptotic distribution of the proposed weighted distributed estimator are derived, as well as the asymptotic equivalence between the weighted distributed and the generalized method of moment (GMM) estimator (Hansen, 1982).

- We also propose a debiased weighted distributed estimator with a data splitting mechanism on each data block to remove the dependency between the bias correction and the weights used to tackle the heterogeneity. The debiased weighted distributed estimator is asymptotically as efficient as the WD estimator but allows quicker growth for the number of blocks $K = o(N^{2/3})$. The bias correction is also applied to the split-and-conquer formulation, leading to a more communication-efficient debiased split-and-conquer estimator.
2. Preliminaries

Suppose that there is a large data sample of size $N$, which is divided into $K$ data blocks of sizes $\{n_k\}_{k=1}^K$ such that $N = \sum_{k=1}^K n_k$ and let $n = NK^{-1}$ be the average sample size of the data blocks. For the relative sample sizes among data blocks, we assume the following

**Assumption 1** There exist $c, C > 0$ such that $c \leq n_{k_1}/n_{k_2} \leq C$ for all pairs of $(k_1, k_2)$.

The $k$-th data block consists of a sub-sample $\{X_{k,i}\}_{i=1}^{n_k}$ which are independent and identically distributed (IID) random vectors from a probability space $(\Omega, \mathcal{F}, P)$ to $(\mathbb{R}^d, \mathbb{R}^d)$ with $F_k$ as the distribution. The $K$ distributions $\{F_k\}_{k=1}^K$ share a common parameter $\phi \in \mathbb{R}^{p_1}$, while each $F_k$ has another parameter $\lambda_k \in \mathbb{R}^{p_2}$ specific to $F_k$. The parameters of interests in the $k$-th block are $\hat{\theta}_k = (\phi^T, \lambda_k^T)^T \in \mathbb{R}^p$ where $p = p_1 + p_2$, and the overall parameters of interests are $\theta = (\phi^T, \lambda_1^T, \lambda_2^T, \ldots, \lambda_K^T)^T \in \mathbb{R}^{p_1 + Kp_2}$.

Suppose there is a common objective function $M(X; \phi, \lambda_k)$ that is convex with respect to the parameter $\theta_k = (\phi^T, \lambda_k^T)^T$ and facilitates the statistical optimization in each data block. In general, the loss function can be made block-specific, say $M_k(\cdot; \cdot)$ function. Indeed, the presence of the heterogeneous local parameters $\{\lambda_k\}_{k=1}^K$ leads to different $M_k(x, \phi) = M(x; \phi, \lambda_k)$ for the inference on $\phi$, which connects to the multi-task learning. In the $k$-th data block the true parameter $\theta^*_k = (\phi^T, \lambda_k^T)^T$ is defined as the unique minimum of the expected objective function, namely

$$\theta^*_k = \arg \min_{\theta_k \in \Theta_k} E_{F_k}(M(X_{k,1}; \phi, \lambda_k)).$$

The true common parameter $\phi^*$ appears in all $\theta^*_k$, and the block-specific $\{\lambda^*_k\}_{k=1}^K$ may differ from each other. The entire true parameters $\theta^* = (\phi^T, \lambda_1^T, \cdot \cdot \cdot, \lambda_K^T)^T$, can be also identified as

$$\theta^* = \arg \min_{\theta \in \Theta} \sum_{k=1}^K \gamma_k E_{F_k}(M(X_{k,1}; \phi, \lambda_k)),$$

where $\gamma_k = \lim_{k \to \infty} (n_k/N)$ is the asymptotic proportion of the local sample size $n_k$ relative to the total sample size $N$ such that $\sum_{k=1}^K \gamma_k = 1$.

Our study is conducted under the semiparametric setting, which does not assume knowledge of the data distribution of $X$ but knowing the functional form of $M(\cdot; \cdot)$, and hence semiparametric. It is a setting situated between the parametric and the nonparametric settings. Parametric setting means a full knowledge in the data generation distribution, which means that in the context of the $M$-estimation one knows the form of each $P_k$ up to some parameter $\theta$ so that $P_k = P_k(\theta)$, where $P_k(\theta)$ is a parametrized form of $P_k$. In contrast, the nonparametric setting is where neither the form of the target quantities nor the distribution of $X$ is known. The difficulty with the nonparametric setting is due to not knowing the forms of the data distribution and the quantities of interests.

If the data could be shared across the data blocks, we would attain the conventional full sample estimator

$$\hat{\theta}_{\text{full}} = \arg \min_{\theta \in \Theta} \sum_{k=1}^K \sum_{i=1}^{n_k} M(X_{k,i}; \phi, \lambda_k), \quad \text{where} \quad \hat{\theta}_{\text{full}} = (\hat{\phi}_{\text{full}}^T, \hat{\lambda}_{1,\text{full}}^T, \cdot \cdot \cdot, \hat{\lambda}_{K,\text{full}}^T)^T,$$

which serves as a benchmark for distributed estimators. The estimating equations for the full sample estimators are

$$\begin{align*}
\sum_{k=1}^K \sum_{i=1}^{n_k} \psi_\phi(X_{k,i}; \phi, \lambda_k) &= 0, \\
\sum_{i=1}^{n_k} \psi_\lambda(X_{k,i}; \phi, \lambda_k) &= 0 \quad k = 1, \ldots, K,
\end{align*}$$

(1)
where \( \psi_{\theta}(X_{k,i}; \phi, \lambda_k) = \partial M(X_{k,i}; \phi, \lambda_k)/\partial \phi \) and \( \psi_{\lambda}(X_{k,i}; \phi, \lambda_k) = \partial M(X_{k,i}; \phi, \lambda_k)/\partial \lambda_k \) are the score functions. The above full sample estimation is not attainable for the distributed situations due to privacy or the costs associated with the data communication. The distributed estimation first conducts local estimation on each data block, namely the local estimator \( \hat{\theta}_k = (\hat{\phi}_k^T, \hat{\lambda}_k^T)^T = \arg\min_{\theta_k \in \Theta_k} \sum_{i=1}^{n_k} M(X_{k,i}; \theta_k) \) with the corresponding estimating equations

\[
\begin{align*}
\sum_{i=1}^{n_k} \psi_{\phi}(X_{k,i}; \phi_k, \lambda_k) &= 0, \\
\sum_{i=1}^{n_k} \psi_{\lambda}(X_{k,i}; \phi_k, \lambda_k) &= 0,
\end{align*}
\]

and the split-and-conquer estimator for the common parameter \( \phi \) is

\[
\hat{\phi}_{\text{SaC}} = \frac{1}{N} \sum_{k=1}^{K} n_k \hat{\phi}_k.
\]

The heterogeneity among the distributions of the data blocks calls for study the relative efficiency and the estimation errors, which are the focus of this paper. We are to show that the split-and-conquer estimator (3) may not be the best formulation for estimating \( \phi \). Throughout this paper, unless otherwise stated, \( \| \cdot \|_2 \) represents the \( \ell_2 \) norm of a vector and a matrix. We will use \( C \) and \( C_1 \) to denote positive constants independent of \((n_k, K, N)\).

An important question is the efficiency and the estimation errors of the split-and-conquer estimator (3) relative to the full sample estimator \( \hat{\phi}_{\text{full}} \). For the homogeneous case, Chen and Peng (2021) found that for the asymptotic symmetric statistics, the split-and-conquer estimator (3) attains the same efficiency as the full sample estimator in the non-degenerate case but encounters an efficiency loss in the degenerate case \(^1\), due to a lack of communication among different data blocks. Zhang et al. (2013) derived the mean squared error bound for the split-and-conquer estimator in the homogeneous case and showed that whenever \( K = O(N^{1/2}) \), the split-and-conquer estimator achieves the best possible rate of convergence when all \( N \) data are accessible.

Consider the estimating equations of the full sample statistical optimization

\[
\Psi_N(X; \theta) = \left( \frac{\sum_{k=1}^{K} \sum_{i=1}^{n_k} \psi_{\phi}(X_{k,i}; \phi, \lambda_k)}{\sum_{i=1}^{n_1} \psi_{\phi}(X_{1,i}; \phi, \lambda_1)}, \ldots, \frac{\sum_{i=1}^{n_K} \psi_{\phi}(X_{K,i}; \phi, \lambda_K)}{\sum_{i=1}^{n_1} \psi_{\phi}(X_{1,i}; \phi, \lambda_1)} \right).
\]

Let \( \Psi_{\theta}(\theta_k) = \nabla_{\theta_k} E(M(X_{k,1}; \theta_k)) \) and \( J_k(\theta_k) = \nabla_{\theta_k}^T \Psi_{\theta}(\theta_k) \) be the first and second order gradients of the \( k \)-th population objective function, respectively, whose matrix forms are:

\[
\Psi_{\theta}(\theta_k) = (\Psi_{\phi}(\theta_k)^T, \Psi_{\lambda}(\theta_k)^T)^T, \quad J_k(\theta_k) = \begin{pmatrix} \Psi_{\phi}(\theta_k) & \Psi_{\lambda}(\theta_k) \\ \Psi_{\phi}^T(\theta_k) & \Psi_{\lambda}^T(\theta_k) \end{pmatrix}.
\]

\(^1\) The symmetric statistics admits the expansion \( T_n = \theta + n^{-1} \sum_{i=1}^{n} \alpha(X_i; F) + n^{-2} \sum_{1 \leq i < j \leq n} \beta(X_i, X_j; F) + R_n \) (Lai and Wang, 1993), which covers the U-statistics and M-estimator as special cases. The functions \( \alpha(x; F) \) and \( \beta(x, y; F) \), depending on the underlying data distribution \( F \), are known measurable functions of \( x \) and \( y \), satisfying \( E(\alpha(X_1; F)) = 0 \) and \( \text{Var}(\alpha(X_1; F)) = \sigma_{\alpha}^2 \in [0, \infty) \) and \( \beta(x, y; F) \) being symmetric in \( x \) and \( y \) such that \( E(\beta(X_1, X_2; F) | X_1) = 0 \) and \( \text{Var}(\beta(X_1, X_2; F)) = \sigma_{\beta}^2 \in [0, \infty) \). The degenerate and non-degenerate case correspond to the \( \sigma_{\alpha}^2 = 0 \) and \( \sigma_{\alpha}^2 > 0 \) cases, respectively.
Let $J_{\phi|\lambda}(\theta_k) = \Psi_{\phi}(\theta_k) - \Psi_{\phi}(\theta_k)\Psi_{\lambda}(\theta_k)^{-1}\Psi_{\phi}(\theta_k)$, $J_{\lambda|\phi}(\theta_k) = \Psi_{\lambda}(\theta_k) - \Psi_{\phi}(\theta_k)\Psi_{\phi}(\theta_k)^{-1}\Psi_{\lambda}(\theta_k)$, $S_{\phi}(X_{k,i};\theta_k) = \psi_{\phi}(X_{k,i};\theta_k) - \Psi_{\phi}(\theta_k)\Psi_{\lambda}(\theta_k)^{-1}\psi_{\lambda}(X_{k,i};\theta_k)$ and $S_{\lambda}(X_{k,i};\theta_k) = \psi_{\lambda}(X_{k,i};\theta_k) - \Psi_{\phi}(\theta_k)\Psi_{\phi}(\theta_k)^{-1}\psi_{\phi}(X_{k,i};\theta_k)$. Then, apply Taylor’s expansion to obtain (see Appendix A.1)

$$\hat{\phi}_{\text{full}} - \phi^* = -\left(\sum_{k=1}^{K} \frac{n_k}{N} J_{\phi|\lambda}(\theta_k)\right)^{-1} N^{-1}\left(\sum_{k=1}^{K} \sum_{i=1}^{n_k} S_{\phi}(X_{k,i};\theta_k^*)\right) + o_p(N^{-1/2}).$$

For the local estimator $(\hat{\phi}_k, \hat{\lambda}_k)$ that solves (2), the same derivation leads to

$$\begin{align*}
\phi_k - \phi^* & = -n_k^{-1} J_{\phi|\lambda}(\theta_k^*)^{-1} \sum_{i=1}^{n_k} S_{\phi}(X_{k,i};\theta_k^*) + o_p(n_k^{-1/2}), \\
\lambda_k - \lambda_k^* & = -n_k^{-1} J_{\lambda|\phi}(\theta_k^*)^{-1} \sum_{i=1}^{n_k} S_{\lambda}(X_{k,i};\theta_k^*) + o_p(n_k^{-1/2}).
\end{align*}$$

Our analysis requires the following conditions.

**Assumption 2 (Identifiability)** The parameters $\theta_k^* = (\phi^*, \lambda_k^*)$ is the unique minimizer of $M_k(\theta_k) = E(M(X_{k,1};\theta_k))$ for $\theta_k \in \Theta_k$.

**Assumption 3 (Compactness)** The true parameter $\theta_k^*$ is an interior point of the parameter space $\Theta_k$ which is a compact and convex set in $\mathbb{R}^p$, and $\sup_{\theta_k \in \Theta_k} \|\theta_k - \theta_k^*\|_2 \leq r$ for all $k \geq 1$ and some $r > 0$. The true common parameter $\phi^*$ is an interior point of a subset $\Phi \subset \Theta_k$.

**Assumption 4 (Local strong convexity)** The population objective function on the $k$-th data block $M_k(\theta_k) = E(M(X_{k,1};\theta_k))$ is twice differentiable, and there exists a constant $\rho_+ > 0$ such that $\nabla_{\theta_k}^2 M_k(\theta_k^*) \succeq \rho_- I_{p \times p}$. Here $A \succeq B$ means $A - B$ is a positive semi-definite matrix.

**Assumption 5 (Smoothness I)** The objective function on the $k$-th data is twice differentiable with respect to $\theta_k \in U_k$, where $U_k = \{\theta_k \mid \|\theta_k - \theta_k^*\|_2 \leq \rho\}$ and $\rho$ is a positive constant. There are positive constants $R, L, v$ and $v_1$ such that

$$E\left(\|\nabla_{\theta_k} M(X_{k,1};\theta_k^*)\|_{2^{v_1}}\right)^2 \leq R^{2v_1} \quad \text{and} \quad E\left(\|\nabla_{\theta_k}^2 M(X_{k,1};\theta_k^*) - \nabla_{\theta_k}^2 M(\theta_k^*)\|_{2}^2\right) \leq L^{2v}$$

for all $k \geq 1$. There also exist a positive function $G(\cdot)$ and a corresponding positive constant $G$ such that

$$\|\nabla_{\theta_k}^2 M(x;\theta_k) - \nabla_{\theta_k}^2 M(x;\theta_k^*)\|_2 \leq G(x)\|\theta_k - \theta_k^*\|_2$$

for all $\theta_k, \theta_k' \in U_k$ and $x \in \mathbb{R}^d$, and $E(G(X_{k,1})^{2v}) \leq G^{2v}$.

Assumptions 1-5 are standard ones on the parameter space and population objective functions for the homogeneous case (Jordan et al. 2019). In the heterogeneous case, Duan et al. (2021) requires the parameter space for the common parameter to be bounded, i.e. $\|\phi - \phi^*\| \leq r$ under a fully parametric setting, while we need the overall parameter space to be bounded. The stronger condition is needed since we do not fully specify the distributions $\{F_k\}_{k=1}^K$ and it will be used when we derive the mean squared error bound for the proposed weighted distributed estimator in Section 4. Besides, since the differentiability of the objective function is assumed locally, we need Assumption 5 to define a high probability event in (34), under which all the derivatives are well-defined.
3. Full Sample versus split-and-conquer Estimation

When the full data communication is available, one would in general prefer making the estimation based on the pooled data, namely solving the estimating equations (1) rather than the local estimating equations (2). This choice is based on the common belief that the estimator based on the pooled data, namely solving the estimating equations (1) rather than the local estimation of the weighted distributed estimator. We will show more general results and allow diverging in the subsequent theoretical results and the supplementary material (see Lemma B.2 for the uniform consistency of \(\{\theta_k\}_{k=1}^K\) under diverging \(K\) and the relationship between the divergence rate and the smoothness factors \(v, v_1\)). In particular, we will discuss how to improve the divergence rate of \(K\) in Section 5.

**Proposition 1** Under Assumptions 1 - 4 and Assumption 5 with \(v, v_1 \geq 1\), and if \(K\) is fixed, then \(\hat{\theta}_k \to \theta^*_k\) and \(\hat{\theta}_{\text{full}} \to \theta^*\) in probability; \(\hat{\phi}^{\text{SaC}} = (1/N) \sum_{k=1}^K n_k \hat{\phi}_k\) and \(\hat{\phi}_{\text{full}}\) are consistent to \(\phi^*\).

**Theorem 2** Under Assumptions 1 - 4 and Assumption 5 with \(v, v_1 \geq 2\), if \(K\) is fixed and \(n_k/N \to \gamma_k \in (0, 1)\) for a set of constants \(\{\gamma_k\}_{k=1}^K\), then

\[
\sqrt{N} (\hat{\phi}^{\text{SaC}} - \phi^*) \to N \left(0_{p_1}, \sum_{k=1}^K \gamma_k J_{\phi|\lambda}(\theta^*_k)^{-1} \Sigma_k (\theta^*_k) J_{\phi|\lambda}(\theta^*_k)^{-1} \right)
\]

and

\[
\sqrt{N} (\hat{\phi}_{\text{full}} - \phi^*) \to N \left(0_{p_1}, \left(\sum_{k=1}^K \gamma_k J_{\phi|\lambda}(\theta^*_k)^{-1} \sum_{k=1}^K \gamma_k \Sigma_k (\theta^*_k) \sum_{k=1}^K \gamma_k J_{\phi|\lambda}(\theta^*_k)^{-1} \right) \right),
\]

where \(\Sigma_k = \text{Var} (S_{\phi}(X_{k,1}; \theta^*_k))\).

Theorem 2 suggests that the asymptotic variance of the full sample estimator may surpass that of the SaC estimator. To appreciate this, define \(V(\Sigma, A) = (A^T)^{-1} \Sigma A^{-1}\) as a mapping from \(\mathbb{S}_{p_1} \times \text{GL}(\mathbb{R}^{p_1})\) to \(\mathbb{S}_{p_1} \times \text{GL}(\mathbb{R}^{p_1})\), where \(\mathbb{S}_{p_1} \times \text{GL}(\mathbb{R}^{p_1})\) denote the symmetric positive definite matrices and invertible real matrices of order \(p_1\), respectively. Since \(\Sigma_{k=1}^K \gamma_k = 1\) and \(\gamma_k > 0\), the asymptotic variance of \(\hat{\phi}^{\text{SaC}}\) can be interpreted as a convex combination of function values \(\{V(\Sigma_k(\theta^*_k), J_{\phi|\lambda}(\theta^*_k))\}_{k=1}^K\) and that of \(\hat{\phi}_{\text{full}}\) can be expressed as \(V(\sum_{k=1}^K \gamma_k \Sigma_k (\theta^*_k), \sum_{k=1}^K \gamma_k J_{\phi|\lambda}(\theta^*_k))\). However, \(V(\cdot, \cdot)\) is not convex with respect to its arguments \((\Sigma, A)\), which means that

\[
\left(\sum_{k=1}^K \gamma_k J_{\phi|\lambda}(\theta^*_k)^{-1} \left(\sum_{k=1}^K \gamma_k \Sigma_k (\theta^*_k) \right) \left(\sum_{k=1}^K \gamma_k J_{\phi|\lambda}(\theta^*_k)^{-1}\right)^{-1}\right) \neq \left(\sum_{k=1}^K \gamma_k J_{\phi|\lambda}(\theta^*_k)^{-1} \Sigma_k (\theta^*_k) J_{\phi|\lambda}(\theta^*_k)^{-1}\right).
\]

In other words, \(\hat{\phi}_{\text{full}}\) is not necessarily more efficient than \(\hat{\phi}^{\text{SaC}}\) under heterogeneity. In contrast, in the homogeneous setting \((J_{\phi|\lambda}(\theta^*_k), \Sigma_k (\theta^*_k))\) are all equal for different \(k\), then the non-convexity of
\( V(\cdot, \cdot) \) does not matter anymore and the first-order equivalence between the SaC estimator and the full sample estimator holds as long as \( K = o(N^{1/2}) \). A conclusion from Theorem 2 is that naively using the pooled data to solve the statistical optimization problem may not be a good choice when the underlying distributions of the data are heterogeneous.

To gain confirmation of Theorem 2 we consider the errors-in-variables model. Suppose there are \( K \) independent data blocks \( \{(X_{k,i}, Y_{k,i})\}_{i=1}^N \) for \( k = 1, \ldots, K \), where \((X_{k,i}, Y_{k,i})\) are IID and generated from

\[
X_k = Z_k + e_k, \quad Y_k = \phi^* + \lambda_k^* Z_k + f_k,
\]

where \( \{Z_k\}_{k=1}^K \) are random variables whose measurements \( \{(X_k, Y_k)\}_{k=1}^K \) are subject to errors \( \{(e_k, f_k)\}_{k=1}^K \), and \((e_k, f_k)\) are bivariate normally distributed with zero mean and covariance matrix \( \sigma^2 I_2 \) and is independent of \( Z \). Obviously, \( \phi^* \) is the common parameter across all data blocks while \( \lambda_k^* (\lambda_k^* > 0) \) represents the block specific parameter. The condition \( \text{Var}(e) = \text{Var}(f) \) is assumed to avoid any identification issue arising when \( Z \) is also normally distributed (Reiersol, 1950). We consider the approach in Example 5.26 of van der Vaart (1999) as detailed in Appendix A.2, which leads to the \( M \)-function

\[
M(X_k, Y_k; \theta_k) = \frac{1}{(1 + \lambda_k^2)} (\lambda_k X_k - (Y_k - \phi))^2.
\]

For simplicity we assume \( K = 2 \), then from Theorem 2 we have

\[
\begin{align*}
\text{Var}(\hat{\phi}_{\text{full}}) & \approx \left( \frac{\sigma^2 E(Z^2)}{\text{Var}(Z)} \right) \frac{2}{1 + \lambda_1^2 + 1 + \lambda_2^2} + \frac{\sigma^4 E(Z^2)^2}{\text{Var}^2(Z)} \left( \frac{2}{1 + \lambda_1^2 + 1 + \lambda_2^2} \right)^2 \frac{1}{N}, \\
\text{Var}(\hat{\phi}_{\text{SaC}}) & \approx \left( \frac{\sigma^2 E(Z^2)}{\text{Var}(Z)} \right) \frac{2}{(1 + \lambda_1^2) + (1 + \lambda_2^2)} + \frac{\sigma^4 E(Z^2)^2}{\text{Var}^2(Z)} \frac{1}{N}.
\end{align*}
\]

Note that the coefficients to \( \sigma^2 E(Z^2)/\text{Var}(Z) \) in the first terms of the variances are harmonic and arithmetic means of \( \{1 + \lambda_1^2, 1 + \lambda_2^2\} \), respectively. Hence, the coefficient in the first term of \( \text{Var}(\hat{\phi}_{\text{SaC}}) \) is larger than that in \( \text{Var}(\hat{\phi}_{\text{full}}) \). The second terms of the variances involves \( (E(Z))^2 \) as a multiplicative factor. Thus, if the unobserved \( Z \) has zero mean, the full-sample estimator will be at least as good as the SaC estimator in terms of variance when the full sample size \( N \) goes to infinity. However, the situation may change when \( E(Z) \neq 0 \), because the second term of \( \text{Var}(\hat{\phi}_{\text{full}}) \) has a factor which is the square of a ratio between the quadratic mean and the arithmetic mean of \( \{ \frac{1}{1 + \lambda_1^2}, \frac{1}{1 + \lambda_2^2} \} \). The factor is larger than or equal to 1, where the equality holds if and only if \( \lambda_1^* = \lambda_2^* \) namely the homogeneous case. In the heterogeneous case, by adjusting \( \frac{\sigma^4 E(Z^2)^2}{\text{Var}^2(Z)} / \frac{\sigma^2 E(Z^2)}{\text{Var}(Z)} \), we can find cases such that \( \lambda_1^* \neq \lambda_2^* \) so that the full sample estimator has a larger variance than the SaC estimator. Appendix C.1 displays such cases.

4. Weighted Distributed Estimator

That the full sample estimator \( \hat{\phi}_{\text{full}} \) under heterogeneity may be less efficient than the simple averaged \( \hat{\phi}_{\text{SaC}} \) suggests that the wisdom formulated in the homogeneous context may not be applicable.

\(^2\) When \( Z \) is normal, \( (X, Y) \) is also jointly normal, whose distribution can be fully characterized by the five parameters \((E(X), \text{Var}(X), E(Y), \text{Var}(Y), E(XY))\). Now, if we do not require \( \text{Var}(e) = \text{Var}(f) \), there will be six unknown parameters: \((\text{Var}(e), \text{Var}(f), E(Z), \text{Var}(Z), \phi, \lambda)\), leading to identification issues. For more detailed discussions on the errors-in-variables model, see Fuller (1987).
to the heterogeneous case. How to better aggregate the local estimators \( \{ \hat{\phi}_k \}_{k=1}^K \) for more efficient estimation is the focus of this section.

### 4.1 Formulation and Results

Consider a class of estimators formed by linear combinations of the local estimators \( \{ \hat{\phi}_k \}_{k=1}^K \):

\[
\{ \phi_{w}^{\text{SaC}} \mid \phi_{w}^{\text{SaC}} = \sum_{k=1}^K W_k \hat{\phi}_k, W_k \in \mathbb{R}^{p_1 \times p_1}, \sum_{k=1}^K W_k = I_{p_1 \times p_1} \}.
\]

We want to minimize the asymptotic variance of \( \phi_{w}^{\text{SaC}} \) with respect to the weighting matrices \( \{ W_k \}_{k=1}^K \). It may be shown from Theorem 2 that \( \text{Var}(\phi_{w}^{\text{SaC}}) \approx \sum_{k=1}^K n_k^{-1} W_k A_k^{-1} \Sigma_k (A_k^T)^{-1} W_k^T \), where \( A_k = J_{\phi \lambda}(\theta_k^*) \) and \( \Sigma_k = \text{Var}(S_\phi(X_{k,i}; \theta_k^*)) \). It is noted that the asymptotic variance is defined via the asymptotic normality of the statistical optimization. For the time being, \( A_k \) and \( \Sigma_k \) are assumed known and we denote \( H_k = A_k^{-1} \Sigma_k (A_k^T)^{-1} \). We choose the trace operator as a measure of the size of the covariance matrix, which leads to a minimization problem:

\[
\text{Minimize} \quad \text{trace} \left( \sum_{k=1}^K n_k^{-1} W_k H_k W_k^T \right) \quad \text{s.t.} \quad \sum_{k=1}^K W_k = I_{p_1 \times p_1}. \tag{9}
\]

It is a convex optimization problem and can be solved via the Lagrangian multiplier method, which gives the optimal weighting matrices \( W_k^* = (\sum_{k=1}^K n_k H_k)^{-1} N_k H_k^T \). If we replace the trace with the Frobenius norm in (9), the same solution is attained as shown in Appendix A.3. The split-and-conquer estimator with the optimal weights \( W_k^* \) is called the weighted distributed estimator and denoted as \( \hat{\phi}^{\text{WD}} \), which is at least as efficient as \( \hat{\phi}^{\text{SaC}} \) by construction.

To compare the statistical efficiency between \( \hat{\phi}_{\text{full}} \) and \( \hat{\phi}^{\text{WD}} \), we note that their covariances

\[
\text{Var}(\hat{\phi}_{\text{full}}) \approx \left( \sum_{k=1}^K n_k A_k \right)^T \left( \sum_{k=1}^K n_k \Sigma_k \right)^{-1} \left( \sum_{k=1}^K n_k A_k \right)^{-1} \quad \text{and}
\]

\[
\text{Var}(\hat{\phi}^{\text{WD}}) \approx \left( \sum_{k=1}^K n_k A_k^T \Sigma_k^{-1} A_k \right)^{-1}, \quad \text{respectively.} \tag{10}
\]

Define \( \tilde{V}(\Sigma, A) = A^T \Sigma^{-1} A \), which is a generalized convex function with respect to the matrix inequality shown in Lemma B.1 Applying Jensen’s inequality leads to the conclusion that the weighted distributed estimator is at least as efficient as the full sample estimator \( \hat{\phi}_{\text{full}} \). Thus, the estimating equations (4) obtained from the first-order derivatives of the simple summation of local objectives \( \sum_{k=1}^K n_k M(X_{k,i}; \theta_k) \) may not be the best formulation. In contrast, the weighted distributed estimator exploits the potential efficiency gain from the heterogeneity by re-weighting of the local estimators, which is why the full sample estimator may not be as efficient as the weighted distributed estimator.

### 4.2 Likelihood and Quasi-likelihood

The above results lead us to wonder whether the weighted distributed estimator can also be more efficient than the full sample estimator under the heterogeneity in a fully parametric setting. The answer is negative as shown below.
When the distribution of $X_{k,i}$ is fully parametric with density function $f(\cdot; \phi, \lambda_k)$, the Fisher information matrix in the $k$-th data block is

$$I(\theta_k) = I(\phi, \lambda_k) = \begin{bmatrix} I_{\phi\phi} & I_{\phi\lambda_k} \\ I_{\lambda_k\phi} & I_{\lambda_k\lambda_k} \end{bmatrix} = -E \left( \begin{bmatrix} \frac{\partial^2}{\partial \phi^2} \log f(X_{k,1}; \theta_k) \\ \frac{\partial^2}{\partial \lambda_k^2} \log f(X_{k,1}; \theta_k) \end{bmatrix} \right),$$

and the partial information matrix $I_{\phi|\lambda_k} = I_{\phi\phi} - I_{\phi\lambda_k} I_{\lambda_k\lambda_k}^{-1} I_{\lambda_k\phi}$.

Now, the objective function for the statistical optimization is $M(X_{k,i}; \phi, \lambda_k) = -\log f(X_{k,i}; \phi, \lambda_k)$. Routine derivations show that $\Sigma_k = \text{Var}(S_{\phi}(X_{k,1}; \theta^*_k)) = I_{\phi|\lambda_k}$ and $A_k = I_{\phi|\lambda}(\theta^*_k) = I_{\phi|\lambda_k}$. Hence, $\text{Var}(\hat{\phi}_{\text{full}}) \approx \text{Var}(\hat{\phi}_{\text{WD}}) \approx \left( \sum_{k=1}^K n_k I_{\phi|\lambda_k} \right)^{-1}$ and $\text{Var}(\hat{\phi}_{\text{SaC}}) \approx (1/N^2) \sum_{k=1}^K n_k I_{\phi|\lambda_k}^{-1}$. A direct application of Lemma B.1 shows that $\left( \sum_{k=1}^K n_k I_{\phi|\lambda_k} \right)^{-1} \preceq (1/N^2) \sum_{k=1}^K n_k I_{\phi|\lambda_k}^{-1}$. Thus, the full sample maximum likelihood estimator automatically adjusts for the heterogeneity and has the same asymptotic efficiency as that of the weighted distributed estimator. Both estimators are at least as efficient as the split-and-conquer estimator $\hat{\phi}_{\text{SaC}}$. The same is true for the quasi-likelihood estimation with independent observations (see Appendix A.4).

A close examination reveals that the underlying reason for the asymptotic equivalence between the weighted distributed estimator and the likelihood-based full sample estimators is that the two statistical optimization functions satisfy the second-order Bartlett’s identity (Bartlett, 1953; McCullagh 1983): $E \left( \nabla M(X_k, \theta^*_k) \nabla M(X_k, \theta^*_k)^T \right) = E \left( \nabla^2 M(X_k, \theta^*_k) \right)$. By the asymptotic variance formula of the estimator and Lemma B.1, it is apparent that Bartlett’s identity can be relaxed by allowing a factor $\gamma \neq 0$ such that

$$E \left( \nabla M(X_k, \theta^*_k) \nabla M(X_k, \theta^*_k)^T \right) = \gamma E \left( \nabla^2 M(X_k, \theta^*_k) \right).$$

An example of such cases is the least square estimation in the parametric regression with homoscedastic and non-autocorrelated residuals in Appendix A.5. Otherwise, the full sample least square estimator may not be efficient and there is an opportunity for the weighted least square estimation such as the case in the errors-in-variables model (6). Thus, if $M(x_k, \theta_k)$ satisfies (11), $\hat{\phi}_{\text{full}}$ attains the same statistical efficiency as $\hat{\phi}_{\text{WD}}$.

### 4.3 Relation to Generalized Method of Moment Estimation

To further justify the statistical efficiency of the weighted distributed estimation, we consider the generalized method of moment (GMM) estimator (Hansen 1982), which has certain optimal properties for the semiparametric inference that the weighted distributed estimation can compare with, despite it requires full data sharing.

The score functions of the statistical optimization on each data block are aggregated to form the moment equations

$$\begin{cases} \sum_{i=1}^{n_k} \psi_{\phi}(X_{k,i}; \phi, \lambda_k) = 0, \\ \sum_{i=1}^{n_k} \psi_{\lambda}(X_{k,i}; \phi, \lambda_k) = 0, \quad k = 1, \ldots, K, \end{cases}$$

which have $pK$ estimating equations, where the dimension of $\theta^*$ is $pK - (K - 1)p_1$. Thus, the parameter is over-identified, offering potential efficiency gain for the generalized method of moment.

The GMM estimation based on the moment restrictions (12) solves the minimization problem

$$\hat{\theta}_{\text{GMM}} = \arg \min_{\theta \in \Theta} \left( \tilde{\psi}_N^T(\theta) W_0 \tilde{\psi}_N(\theta) \right),$$

where $W_0$ is a positive definite weighting matrix.
where \( W_0 = \left( \text{Var}(\tilde{\psi}_N(\theta^*)) \right)^{-1} \) is the optimal weighting matrix (Hansen, 1982; Yaron et al., 1996) and

\[
\tilde{\psi}_N(\theta) = \left( \sum_{i=1}^{n_1} \psi_\phi(X_{1,i}; \theta_1)^T, \sum_{i=1}^{n_1} \psi_\lambda(X_{1,i}; \theta_1)^T, \ldots, \sum_{i=1}^{n_K} \psi_\phi(X_{K,i}; \theta_K)^T, \sum_{i=1}^{n_K} \psi_\lambda(X_{K,i}; \theta_K)^T \right)^T.
\]

Let the first \( p_1 \) elements of \( \hat{\theta}_{\text{GMM}} \) be \( \hat{\phi}_{\text{GMM}} \) as an estimator of the common parameter. A derivation in Appendix A.6 shows that \( \text{Var}(\hat{\phi}_{\text{GMM}}) \approx \left( \sum_{k=1}^{K} n_k J_{\phi|\lambda} \sum_{k}^{-1} J_{\phi|\lambda} \right)^{-1} \). Thus, the weighted distributed estimator's asymptotic efficiency is the same as that of \( \hat{\phi}_{\text{GMM}} \). This is encouraging as the weighted distributed estimator does it without requiring so much data sharing among the blocks.

### 4.4 Estimation of weights with one round communication

To formulate the weighted distributed estimator, we have to estimate the optimal weights \( W_k^* = \left( \sum_{k=1}^{K} n_k H_k^{-1} \right)^{-1} n_k H_k^{-1} \). As we will show in Theorem 4, the estimation of the weights will not affect the estimation efficiency of the weighted distributed estimator attained in (10). By the structure of \( W_k^* \), we only need to estimate \( H_k \), the leading principal submatrix of order \( p_1 \) of the asymptotic covariance matrix \( H_k \) of \( \hat{\theta}_k \). Note that

\[
\tilde{H}_k = (\nabla \psi_{\theta}(\hat{\theta}_k))^{-1} E \left( \psi_{\theta_k}(X_{k,1}; \theta_k^*) \psi_{\theta_k}(X_{k,1}; \theta_k^*)^T \right) (\nabla \psi_{\theta}(\hat{\theta}_k))^{-1} = \left( \begin{array}{cc} H_k & \ast \\ \ast & \ast \end{array} \right),
\]

where \( \Psi_{\theta}(\theta_k) = E(\psi_{\theta_k}(X_{k,1}; \theta_k)) \). We can construct a sandwich type estimator (Stefanski and Boos, 2002) to estimate \( \tilde{H}_k \) and then \( H_k \). The procedure to obtain the weighted distributed estimator is summarized in Algorithm 1.

**Input:** Distributed datasets: \( \{X_{k,i}, k = 1, \ldots, K; i = 1, \ldots, n_k\} \)

**Output:** Weighted distributed estimator: \( \tilde{\phi}_{\text{WD}} \)

1. In each data block \( k (k = 1, 2, \ldots, K) \):
   2. Solve (2) and obtain \( \hat{\theta}_k = (\hat{\phi}_k, \hat{\lambda}_k) \);
   3. Calculate \( \tilde{H}_k(\hat{\theta}_k) \), which is the leading principal sub-matrix of order \( p_1 \) of
      \( (\nabla \theta_k \tilde{\psi}_{\theta_k})^{-1} (n_k^{-1} \sum_{i=1}^{n_k} Z(X_{k,i}; \theta_k)) (\nabla \theta_k \tilde{\psi}_{\theta_k})^{-1} \), where \( Z(x, \theta_k) \) is defined in Assumption 6 and \( \tilde{\psi}_{\theta_k} = n_k^{-1} \sum_{i=1}^{n_k} \psi_{\theta_k}(X_{k,i}; \hat{\theta}_k) \);
4. In a central server:
   5. Collect \( (\hat{\phi}_k, \tilde{H}_k(\hat{\theta}_k))^{-1} \) from all the \( K \) data blocks;
   6. Calculate \( \hat{\phi} = \left( \sum_{k=1}^{K} n_k \tilde{H}_k(\hat{\theta}_k) \right)^{-1} \sum_{k=1}^{K} n_k (\tilde{H}_k(\hat{\theta}_k))^{-1} \hat{\phi}_k ;
   7. \( \tilde{\phi}_{\text{WD}} = \hat{\phi}(\hat{\phi} \in \Phi) + \hat{\phi}_{\text{SaC}}(\hat{\phi} \notin \Phi) \), where \( \hat{\phi}_{\text{SaC}} = N^{-1} \sum_{k=1}^{K} n_k \hat{\phi}_k \).

**Algorithm 1:** Weighted Distributed estimator

Step 7 of the algorithm is necessary since there is no guarantee that after weighting the estimator \( \hat{\phi} \) belongs to the set \( \Phi \) as required in Assumption 3. However, the event \( \{\hat{\phi} \notin \Phi\} \) should happen with probability approaching one. Hence, the \( \hat{\phi}_{\text{SaC}}(\hat{\phi} \notin \Phi) \) term is asymptotically negligible. To establish the theoretical properties of the weighted distributed estimator, we impose the following assumptions.
**Assumption 6 (Smoothness II)** Denote \( Z(x, \theta_k) = \nabla_{\theta_k} M(x; \theta_k) \nabla_{\theta_k} M(x; \theta_k)^T \), then there are positive constants \( \rho \) and \( B \), and a positive function \( B(x) \) such that \( Z(x, \theta_k) \) is \( B(x) \)-Lipschitz continuous with respect to \( \theta_k \), in the sense that \( \|Z(x, \theta_k) - Z(x, \theta'_k)\|_2 \leq B(x)\|\theta_k - \theta'_k\|_2 \) for all \( \theta_k, \theta'_k \in U_k = \{ \theta_k \mid \|\theta_k - \theta'_k\|_2 \leq \rho \} \) and \( x \in \mathbb{R}^d \), and \( E(B(X_{k,1})^{2v}) \leq B^{2v} \).

Assumption 6 specifies the Lipschitz continuity of the outer product \( Z(x; \theta_k) \) with respect to \( \theta_k \), which is to control the estimation errors when we estimate the asymptotic covariance matrices of the local estimators \( \{\theta_k\}_{k=1}^K \). Appendix A.7 shows it is valid for the logistic regression model.

**Assumption 7 (Boundeness)** Denote \( \Sigma_{S,k}(\theta_k) = E_{F_k}(E_{\psi_k}(X_{k,1}; \theta_k)E_{\psi_k}(X_{k,1}; \theta_k)^T) \), then there exist constants \( \rho_\sigma, c > 0 \) such that \( \|\Sigma_{S,k}(\theta^*_k)\|_2 \leq \rho_\sigma \) and \( H_k \geq c I_{p_1 \times p_1} \) for \( k \geq 1 \), where \( \theta^*_k \) is the minimizer of the \( k \)-th population objective function and \( H_k = A_k^{-1} \Sigma_k A_k^{-1} \), where \( A_k = J_{\phi(\lambda)}(\theta^*_k) \) and \( \Sigma_k = \text{Var}(S_\phi(X_{k,i}; \theta^*_k)) \).

By \( H_k \)'s definition, \( \|H_k\|_2 \leq \|J_k(\theta^*_k)^{-1}\|_2^2 \|\Sigma_{S,k}(\theta^*_k)\|_2 \leq \rho_\sigma \rho^{-2} \), implying \( H_k^{-1} \geq (\rho^2 / \rho_\sigma) I_{p_1 \times p_1} \).

The above inequality also leads to the inequality \( \|J_k(\theta^*_k)^{-1}\|_2 \geq (c / \rho_\sigma)^{1/2} \), indicating a finite upper bound for the norm of the Hessian, as assumed in Jordan et al. (2019) and Duan et al. (2021). 

**Theorem 3** Under Assumptions 1 - 4 and 7, and Assumptions 5 - 6 with \( v \geq 2 \) and \( v_1 \geq 4 \), for \( n = NK^{-1} \), the mean-squared error of the weighted distributed estimator \( \hat{\phi}^{WD} \) satisfies

\[
E \left( \|\hat{\phi}^{WD} - \phi^*\|_2^2 \right) \leq C_1 \frac{R^2}{nK} + C_2 \left( \frac{L^2 + L^4}{n^2} + \frac{R^2(R^2 + R^6 + G^2)}{n^2} \right) + C_3 \frac{n^3}{n^2} + C_4 K \left( \frac{1 + L^{2v}}{n^v} + \frac{R^{2v_1}}{n^{v_1}} + \frac{R^{2v_1}}{n^{v_1}} \right).
\]

The \( v_1 \) and \( v \) appeared in Assumptions 5 - 6 quantify the moments of the first two orders of the gradients of the \( M \)-function and their corresponding Lipschitz functions. When the number of data blocks \( K = O(N^{1/2}) \) namely \( K = O(n) \), the convergence rate of mean squared error of \( \hat{\phi}^{WD} \) is \( O((nK)^{-1}) \), which is the same as the standard full sample estimator. However, when there are too many data blocks such that \( K \gg n \), the convergence rate is reduced to \( O(n^{-2}) \).

**Theorem 4** Under Assumptions 1 - 4 and 7 and Assumptions 5 - 6 with \( v, v_1 \geq 2 \), if \( K = o(N^{1/2}) \), then \( (\hat{\phi}^{WD} - \phi^*)^T \left( \sum_{k=1}^K n_k H_k^{-1} \right) (\hat{\phi}^{WD} - \phi^*) \to \chi_{p_1}^2 \).

As mentioned before, \( K \) is allowed to diverge with the full sample size at the rate \( o(N^{1/2}) \). Although \( \{H_k\}_{k=1}^K \) have bounded spectral norms, \( \sum_{k=1}^K (n_k/N) H_k^{-1} \) may not converge to a fixed matrix in the presence of heterogeneity. Thus, we can only obtain the asymptotic normality of the standardized \( N^{-1/2} \left( \sum_{k=1}^K (n_k/N) H_k^{-1} \right)^{1/2} (\hat{\phi}^{WD} - \phi^*) \). This is why Theorem 4 is presented in the limiting chi-squared form, which implies that we can construct confidence regions for \( \phi \) with confidence level \( 1 - \alpha \) as

\[
\{ \phi \mid (\hat{\phi}^{WD} - \phi)^T \left( \sum_{k=1}^K n_k H_k^{-1} \right)^{-1} (\hat{\phi}^{WD} - \phi) \leq \chi_{p_1, \alpha}^2 \}
\]

after replacing \( \sum_{k=1}^K n_k H_k^{-1} \) with its sample counterpart \( \sum_{k=1}^K n_k H_k(\hat{\theta}_k)^{-1} \), where \( \chi_{p_1, \alpha}^2 \) is the upper \( \alpha \) quantile of the \( \chi_{p_1}^2 \) distribution. Given the weighted distributed estimator of the common
parameter $\phi^*$, a natural question is whether a more efficient estimator of the block-specific $\lambda_k^*$ can be obtained, if we plug in the weighted distributed estimator to each data block and re-estimate $\lambda_k$: Let $\hat{\lambda}_k^{(2)}$ be the updated estimator, and Theorem 9 in Appendix A.8 will show that $\hat{\lambda}_k^{(2)}$ is not necessarily more efficient than the local estimator $\hat{\lambda}_k$.

5. Debiased Estimator for Diverging $K$

It is noted that $K = o(N^{1/2})$ is required in Theorems 3 and 4 to attain the $O(N^{-1})$ leading order mean squared error and the limiting chi-squared distribution of the weighted distributed estimator $\hat{\phi}^{WD}$. A reason for this requirement is that the bias of the local estimator $\theta_k$ is at order $O_p(n_k^{-1})$, which can not be reduced by the weighted averaging. This leads to the bias of $N^{1/2}(\hat{\phi}^{WD} - \phi^*)$ being at the order $O_p(KN^{-1/2})$, which is not necessarily diminishing to zero unless $K = o(N^{1/2})$. It is worth mentioning that Duan et al. (2021) needed the same $K = o(N^{1/2})$ order in their maximum likelihood estimation framework to obtain the $N^{1/2}$-convergence since Li et al. (2003) showed that the maximum likelihood estimator is asymptotically biased when $K/n \rightarrow C \in (0, +\infty)$. This calls for a bias reduction step for the local estimators before aggregation to allow for a larger $K$.

To facilitate the bias correction, we have to simplify the notation. Suppose $F(\theta)$ is a $p \times 1$ vector function, $\nabla F(\theta)$ is the usual Jacobian whose $l$-th row contains the partial derivatives of the $l$-th element of $F(\theta)$. Then, the matrices of higher derivatives are defined recursively so that the $j$-th element of the $l$-th row of $\nabla^s L(\theta)$ (a $p \times p^s$ matrix) is the $1 \times p$ vector $f_{lj}^s(\theta) = \partial f_{lj}^{s-1}(\theta)/\partial \theta^T$, where $f_{lj}^{s-1}$ is the $l$-th row and $j$-th element of $\nabla^{s-1} F(\theta)$. Let $\otimes$ denote the Kronecker product. Using Kronecker product we can express $\nabla^s F(\theta) = \partial^s F(\theta)/\partial \theta^T \otimes \partial \theta^T \otimes \cdots \otimes \partial \theta^T$. Besides, define $M_{n,k}(\theta_k) = n_k^{-1} \sum_{i=1}^{n_k} M(X_{k;i}; \theta_k)$, $H_{3,k}(\theta_k) = E(\nabla^2_{\theta_k} \psi_{\theta_k}(X_{k,1}; \theta_k))$, $Q_k(\theta_k) = (-E(\nabla_{\theta_k} \psi_{\theta_k}(X_{k,1}; \theta_k)))^{-1}$, $d_{i,k}(\theta_k) = Q_k(\theta_k)\psi_{\theta_k}(X_{k,i}; \theta_k)$ and $v_{i,k}(\theta_k) = \nabla_{\theta_k} \psi_{\theta_k}(X_{k,i}; \theta_k) - \nabla_{\theta_k} \psi_{\theta_k}(X_{k,i}; \theta_k)$. Then, the leading order bias of $\hat{\theta}_k$ (Riplstone et al. 1996) is

$$\text{Bias}(\theta_k) = n_k^{-1} Q_k(\theta_k^*) \left( E(v_{1,k}(\theta_k^*) d_{1,k}(\theta_k^*)) + \frac{1}{2} H_{3,k}(\theta_k^*) E(d_{1,k}(\theta_k^*) \otimes d_{1,k}(\theta_k^*)) \right).$$

Let $B_k(\theta_k) = Q_k(\theta_k)(E(v_{1,k}(\theta_k) d_{1,k}(\theta_k)) + \frac{1}{2} H_{3,k}(\theta_k) E(d_{1,k}(\theta_k) \otimes d_{1,k}(\theta_k)))$, whose first $p_1$ dimension associated with $\phi$ are denoted as $B_{k,1}^i(\hat{\theta}_k)$. An estimator of $B_k(\theta_k)$ is

$$\hat{B}_k(\theta_k) = \hat{Q}_k(\theta_k)(n_k^{-1} \sum_{i=1}^{n_k} \hat{v}_{i,k}(\theta_k^*) \hat{d}_{i,k}(\theta_k) + \frac{1}{2} \hat{H}_{3,k}(\theta_k) n_k^{-1} \sum_{i=1}^{n_k} (\hat{d}_{i,k}(\theta_k) \otimes \hat{d}_{i,k}(\theta_k))) \quad (13)$$

where $\hat{H}_{3,k}(\theta_k) = n_k^{-1} \sum_{i=1}^{n_k} \nabla^2_{\theta_k} \psi_{\theta_k}(X_{k,i}; \theta_k)$, $\hat{Q}_k(\theta_k) = (-n_k^{-1} \sum_{i=1}^{n_k} \nabla_{\theta_k} \psi_{\theta_k}(X_{k,i}; \theta_k))^{-1}$, $\hat{d}_{i,k}(\theta_k) = \hat{Q}_k(\theta_k)\psi_{\theta_k}(X_{k,i}; \theta_k)$ and $\hat{v}_{i,k}(\theta_k) = \nabla_{\theta_k} \psi_{\theta_k}(X_{k,i}; \theta_k)$. Applying it to each data block, we have the bias-corrected local estimator

$$\hat{\theta}_{k,bc} = \hat{\theta}_k - n_k^{-1} \hat{B}_k(\hat{\theta}_k) 1_{E_{k,bc}},$$

where $E_{k,bc} = \{\hat{\theta}_k - n_k^{-1} \hat{B}_k(\hat{\theta}_k) \in \Theta_k\}$, and the indicator function is to ensure that $\hat{\theta}_{k,bc} \in \Theta_k$.

After the local debiased estimators are obtained, we need to aggregate them via the estimated weights. A direct aggregation will invalidate the bias correction due to the dependence between the estimated weights and the local debiased estimator if they are constructed with the same dataset.
The accumulation of dependence over a large number of data blocks can make the bias correction fail. To remove the dependence between the local estimator \( \hat{\theta}_{k,bc} \) and the estimated local weights \( \hat{W}_k = \left( \sum_{s=1}^{K} \hat{H}_s(\hat{\theta}_s)^{-1} \right)^{-1} \hat{H}_k(\hat{\theta}_k)^{-1} \), we divide each local dataset \( \{X_{ki}\}_{i=1}^{n_k} \) to two basically equal-sized splits \( D^s_k = \{X_{ki}\}_{i=1}^{n_k/2}, s = 1, 2 \). For \( s = 1, 2 \), we calculate the local estimators \( \hat{\theta}_{k,s} \) and obtain \( \hat{H}_{k,s}(\hat{\theta}_{k,s}) \), which is the first \( p_1 \) principal sub-matrix of

\[
(\nabla_{\hat{\theta}_k} \hat{\Psi}_{\hat{\theta}_k})^{-1} \left( (2/n_k) \sum_{i=1}^{n_k/2} \psi_{\theta_k}(X_{ki}; \hat{\theta}_{k,s}) \psi_{\hat{\theta}_k}(X_{ki}; \hat{\theta}_{k,s})^T \right) (\nabla_{\hat{\theta}_k} \hat{\Psi}_{\hat{\theta}_k})^{-T},
\]

where \( \hat{\Psi}_{\hat{\theta}_k} = (2/n_k) \sum_{i=1}^{n_k/2} \psi_{\theta_k}(X_{ki}; \hat{\theta}_{k,s}) \). We perform the local bias correction to \( \hat{\theta}_{k,bc} \) based on a split with the weight obtained by the other, leading to two debiased estimators of the form

\[
\left( \sum_{k=1}^{K} n_k \hat{H}_{k,s}(\hat{\theta}_{k,s})^{-1} \right)^{-1} \sum_{k=1}^{K} n_k (\hat{H}_{k,s}(\hat{\theta}_{k,s}))^{-1} \hat{\theta}_{k,bc}^{bc} \quad \text{for} \quad s = 1, 2.
\]

The two debiased local estimators are averaged to obtain the final debiased weighted distributed estimator, whose procedure is summarized in Algorithm 2. To provide a theoretical guarantee on the bias correction, we need an assumption on the third-order gradient of the \( M \)-function (Zhang et al. 2013), which strengthens a part of Assumption 5.

**Assumption 8 (Strong smoothness)** For each \( x \in \mathbb{R}^p \), the third order derivatives of \( M(x; \theta_k) \) with respect to \( \theta_k \) exist and are \( A(x) - \text{Lipschitz continuous} \) in the sense that

\[
\| (\nabla^2_{\theta_k} \psi_{\theta_k}(x; \theta_k) - \nabla^2_{\theta_k} \psi_{\theta_k}(x; \theta'_k))(u \otimes u) \|_2 \leq A(x)\| \theta_k - \theta'_k \|_2 \| u \|_2^2,
\]

for all \( \theta_k, \theta'_k \in U_k \) defined in Assumption 5 and \( u \in \mathbb{R}^p \), where \( A(x) \) is a positive function, \( E(A(X_{ki})^{2\nu}) \leq A^{2\nu} \) for some \( \nu > 0 \) and \( A < \infty \).

**Theorem 5** Under Assumptions 1 - 4 and 7 - 8, and Assumptions 5 - 6 with \( v, v_1 \geq 4 \),

\[
E \left( \| \hat{\theta}^{\text{dWD}} - \theta^* \|_2^2 \right) \leq C_1 \frac{R^2}{nK} + C_2 \frac{R^2(L^2 + R^2)}{n^2K} + C_3 \frac{G^2R^2(G^2 + R^2 + G^4)}{n^3} + A^2 R^6 + C_4 \frac{C_B}{n^3} + C_5 K \left( \frac{1+L^{2\nu}}{n^{2\nu}} + \frac{R^{2v_1}}{n^{2v_1}} + \frac{R^{2v_1}}{n^{2v_1}} \right),
\]

where the \( C_B \) \( n^{-3} \) term characterizes the error due to the estimation of the bias correction terms \( \{B_k(\theta_{k,bc}^*)\}_{k=1}^{K} \), whose definition can be found in the proof of this theorem presented in the Appendix.

The main difference between the upper bounds in Theorem 5 from that in Theorem 3 for the weighted distributed estimator is the disappearance of the \( O(n^{-2}) \) term for the weighted distributed estimator, which has been absorbed into the \( O((n^2K)^{-1} + n^{-3}) \) terms for the debiased weighted distributed estimator. As shown next, this translates to a more relaxed \( K = o(N^{2/3}) \) condition as compared with the \( K = o(N^{1/2}) \) condition for the weighted distributed estimator in Theorem 4.
**Theorem 6** Under the conditions required by Theorem 5 if \( K = o(N^{2/3}) \),

\[
(\hat{\phi}^{dWD} - \phi^*)^T \left( \sum_{k=1}^{K} n_k H_k(\theta^*_k)^{-1} \right) (\hat{\phi}^{dWD} - \phi^*) \overset{d}{\rightarrow} \chi_{p_1}^2.
\]

Theorem 6 is also formulated in the chi-squared distribution form for the same reason when we formulate Theorem 4. and similar confidence region with confidence level \( 1 - \alpha \) can be constructed as \( \{ \phi \mid (\hat{\phi}^{dWD} - \phi)^T \{ \sum_{k=1}^{K} n_k H_k(\theta^*_k)^{-1} \} (\hat{\phi}^{dWD} - \phi) \leq \chi_{p_1,\alpha}^2 \} \).

The fact that the confidence regions of debiased weighted distributed and weighted distributed estimators use the same standardizing matrix \( \sum_{k=1}^{K} n_k H_k(\theta^*_k)^{-1} \) reflects that both estimators have the same estimation efficiency. However, the debiased version has a more relaxed constraint on \( K = o(N^{2/3}) \) than that of the WD estimator requiring \( K = o(N^{1/2}) \).

Both the debiased and non-debiased weighted distributed estimators are communication efficient as they only require one round of communication. When the communication budget is strictly limited, people may only share the debiased estimators without transmitting the weights. In this case, one may consider the following debiased split-and-conquer estimator

\[
\hat{\phi}^{dSaC} = N^{-1} \sum_{k=1}^{K} n_k (\hat{\theta}_k - n_k^{-1} \hat{B}_k(\hat{\theta}_k) 1_{\mathcal{E}_{k,bc}}),
\]

which only performs bias correction and may be preferable when the heterogeneity is not severe. The asymptotic property of \( \hat{\phi}^{dSaC} \) is summarized in the following theorem.

**Theorem 7** Under the conditions required by Theorem 5 if \( K = o(N^{2/3}) \), the debiased split-and-conquer estimator \( \hat{\phi}^{dSaC} \) satisfies that (i) \( E \left( \| \hat{\phi}^{dSaC} - \phi^* \|_2^2 \right) \leq C_1/(nK) + C_2/(n^2K) + C_3/n^3 \)

and (ii) \( N^2(\hat{\phi}^{dSaC} - \phi^*)^T \left( \sum_{k=1}^{K} n_k H_k(\theta^*_k)^{-1} \right)^{-1} (\hat{\phi}^{dSaC} - \phi^*) \overset{d}{\rightarrow} \chi_{p_1}^2. \)
The corresponding confidence region with confidence level $1 - \alpha$ can be constructed as \( \{ \phi \mid N^2 (\hat{\phi} \text{dSaC} - \phi)^T \left( \sum_{k=1}^{K} n_k \hat{H}_k(\hat{\theta}_k) \right)^{-1} (\hat{\phi} \text{dSaC} - \phi) \leq \chi^2_{p_1, \alpha} \} \). It is noted that the debiased version of the split-and-conquer estimator \( \hat{\phi} \text{dSaC} \) has the same asymptotic distribution as that of \( \hat{\phi} \text{SaC} \), but under a much more relaxed constraint on the divergence rate of \( K \). Hence, the confidence regions based on the split-and-conquer estimator can be constructed in the same way as that based on the weighted distributed estimator with \( \hat{\phi} \text{dSaC} \) replaced by \( \hat{\phi} \text{SaC} \).

To compare with the subsampled average mixture method (SA VGM) estimator proposed in Zhang et al. (2013), which also performs local bias correction but under the homogeneous setting, we have the following corollary to Theorem 7.

**Corollary 8** Under the homogeneous case such that \( \{ X_{k,i}, k = 1, \ldots, K, i = 1, \ldots, n; \} \) are IID distributed, and the assumptions required by Theorem 5,

\[
E \left( \| \hat{\phi} \text{dSaC} - \theta^*_1 \|^2 \right) \leq \frac{2E \left( \| \nabla_{\theta_1} \Psi_\theta(\theta^*_1) \|^{-1} \right.}{nK} \| \psi_{\theta_1}(X_{1,1}; \theta^*_1) \|^2 \frac{1}{n^2 K} + \frac{C_1}{n^2} + \frac{C_2}{n^3},
\]

where \( \theta^*_1 \) is the true parameter for all the \( K \) data blocks.

The SA VGM estimator resamples \( \lfloor rm_k \rfloor \) data points from each data block \( k \) for a \( r \in (0, 1) \) to obtain a local estimator \( \hat{\theta}_{k,r} \) based on the sub-samples, and has the form

\[
\hat{\theta}_{\text{SAVGM}} = \sum_{k=1}^{K} \frac{n_k \hat{\theta}_k - r \hat{\theta}_{k,r}}{1 - r}.
\]

Its mean squared error bound as given in Theorem 4 of Zhang et al. (2013) is

\[
E \left( \| \hat{\theta}_{\text{SAVGM}} - \theta^*_1 \|^2 \right) \leq \frac{2 + 3r}{(1 - r)^2} \frac{E \left( \| \nabla_{\theta_1} \Psi_\theta(\theta^*_1) \|^{-1} \right.}{nK} \| \psi_{\theta_1}(X_{1,1}; \theta^*_1) \|^2 \frac{1}{n^2 K} + \frac{C_1}{n^2} + \frac{C_2}{n^3}.
\]  

Thus, the mean squared error bound (16) of the SAVGM estimator has an inflated factor \((2 + 3r)(1 - r)^{-2} / 2 > 1 \) for \( r \in (0, 1) \) when compared with that of the dSaC estimator, although it is computationally more efficient than the debiased split-and-conquer and debiased weighted distributed estimators as it only draws one subsample in its resampling. For more comparisons between the debiased split-and-conquer estimator and one-step estimators proposed by Huang and Huo (2019), see Appendix A.9.

To facilitate an overall comparison among the existing and the proposed estimators, Table 1 summarizes the non-asymptotic MSE rates of the estimators along with the details on the smoothness condition and the restriction on \( K \), and the statue of statistical efficiency relative to the full sample GMM estimator. It is noted that the smoothness parameters \( v \) and \( v_1 \) can be large if the corresponding random variables are of thin tails, such as the sub-exponential or sub-gaussian distributions, as assumed in Jordan et al. (2019) and Duan et al. (2021). As a result, the smoothness condition becomes trivial, and the \( Kn^{-\min(v,v_1)/2} \) term that appeared in the non-asymptotic rates can be ignored.

6. Numerical Results

The purpose of this section is to examine the numerical performances of the estimators via both the simulation study in Section 6.1 and the real data analysis in Section 6.2.
Table 1: MSE bounds in estimating the common parameter $\phi^*$ by the ideal full sample M-estimator (Full), the distributed SaC, dSaC, WD, dWD and SAVGM estimators, and the estimator in Chen and Peng (2021) (CP). The column headed by “Smoothness” states the needed moment restriction in Assumption 5. The column headed by “K” further states the condition on the block size under which the asymptotic normality of the estimator holds, while that by “Efficiency” indicates if an estimator is statistically efficient (✓) or not (×) relative to the GMM estimator $\hat{\phi}_{GMM}$. For the CP estimator, $\tau_1 \geq 1$ and $\tau_1 = 1$ under the current M-estimation setting.

6.1 Simulation study

We report results from simulation experiments designed to verify the theoretical findings made in the previous sections, which was to evaluate the numerical performance of the proposed weighted distributed (WD), debiased split-and-conquer (dSaC) and debiased weighted distributed (dWD) estimators of the common parameter and compare them with the existing split-and-conquer (SaC) and subsampled average mixture method (SAVGM) (with subsampling rate $r = 0.05$) estimators. Although Zhang’s SAVGM estimator (Zhang et al., 2013) was proposed under the homogeneous setting, but since its main bias correction is performed locally on each data block $k$ as shown in (15), similar theoretical bounds as (16) can be derived without much modifications on the original proof. Throughout the simulation experiments, the results of each simulation setting were based on $B = 500$ number of replications and were conducted in R with a 10-core Intel(R) Core(TM) i9-10900K @3.7 GHz processor. We evaluated the numerical performance of the five estimators for the common parameter $\phi$ under a logistic regression model. For each of $K$ data blocks with $K \in \{10, 50, 100, 250, 500, 1000, 2000\}$, $\{(X_{k,i}, Y_{k,i})\}_{i=1}^n \subset \mathbb{R}^p \times \{0, 1\}$ were independently sampled from the following model:

$$X_{k,i} \sim \mathcal{N}(0_{p \times 1}, 0.75^2 I_{p \times p}) \quad \text{and} \quad P(Y_{k,i} = 1 \mid X_{k,i}) = \frac{\exp(X_{k,i}^T \theta_k^*)}{1 + \exp(X_{k,i}^T \theta_k^*)},$$

where $\theta_k^* = (\phi^T, \lambda_k^T)^T$, $\phi^* = 1$, $\lambda_k^* = (\lambda_{k,1}^*, \lambda_{k,2}^*, \cdots, \lambda_{k,p_2}^*)^T$ and $\lambda_{k,j}^* = (-1)^j 10(1 - 2(k - 1)/(K - 1))$. The sample sizes of the data blocks were equal at $n = NK^{-1}$ with $N = 2 \times 10^6$. Two levels of the dimension $p_2 = 4$ and 10 of the nuisance parameter $\lambda_k$ were considered. Due to space limit, we only report the set of result with $p_2 = 10$ in the main paper. See Appendix C.2 for the result with $p_2 = 4$ and Appendix A.10 for a derivation of the bias correction formula for the logistic model.
Figure 1 reports the root mean squared errors and absolute bias of the estimators when $p_2 = 10$. It is observed that the weighted distributed estimator and the two debiased estimators had smaller root mean squared errors than those of the SaC and SAVGM for almost all the simulation settings. The classical split-and-conquer estimator fared better than Zhang’s SAVGM estimator as $K$ became larger, which is due to the extra variation introduced by the subsampling method as indicated in (16), especially when $K$ is large (the local sample size $n$ is small). It was evident that the WD estimator had much smaller root mean squared errors than the SaC and SAVGM estimators for all the block number $K$, realizing its theoretical promises. In most cases, the WD estimator had smaller bias than the SaC estimator although it was not debiased. The WD estimator was advantageous for $K \leq 250$. In comparison, both bias corrected dWD and dSaC were very effective in reducing the bias of the WD and SaC estimators, respectively, especially for larger $K$ when the bias was more severe. The dWD attained the smallest root mean squared error and the bias in all settings, suggesting the need for conducting both weighting and the bias correction in the distributed inference especially for large $K$. These empirical results were consistent with Theorems 3 and 5, namely the leading root mean squared error term of the WD estimator changes from $O((nK)^{-1})$ to $O(n^{-2})$ when $K$ surpasses the local sample size $n$, while the leading term of the dWD is still $O((nK)^{-1})$ until $K$ is much larger than $n^2$.

Figure 1: Average simulated bias (a) and the root mean squared errors (RMSE) (b) of the weighted distributed (WD) (red circle), the split-and-conquer(SaC) (blue triangle), the debiased split-and-conquer (dSaC) (green square), the debiased weighted distributed (dWD) (purple cross), the subsampled average mixture SAVGM (pink square cross) estimators, with respect to the number of data block $K$ for the logistic regression model with the dimension $p_2$ of the nuisance parameter $\lambda_k$ being 10, and the full sample size $N = 2 \times 10^6$.

We also evaluated the coverage probabilities and widths of the $1 - \alpha$ ($\alpha = 0.01, 0.05, 0.1$) confidence intervals (CIs) of the common parameter based on the asymptotic normality as given after Theorems 4 and 6. The SAVGM estimator was not included as its asymptotic distribution was not made available in Zhang et al. (2013). Table 2 reports the empirical coverage and the average width of the CIs. It is observed that the four types of the CIs all had quite adequate coverage levels when $K \leq 100$. However, for $K \geq 250$, the SaC CIs first started to lose coverage, followed
by those of the WD, while the CIs of the dSaC and dWD estimators can hold up to the promised coverage for all cases of \( K \). Although the dSaC CIs had comparable coverages with the dWD CIs, their widths were much wider than those of the dWD. This was largely due to the fact that the weighted averaging conducted in the weighted distributed estimation reduced the variation and hence the width of the CIs. The widths of the WD CIs were largely the same with those of the dWD, and yet the coverage levels of the dWD CIs were much more accurate indicating the importance of the bias correction as it shifted the CIs without inflating the width.

Table 2: Coverage probabilities and widths (in parentheses, multiplied by 100) of the \( 1 - \alpha \) confidence intervals for the common parameter \( \phi \) in the logistic regression model based on the asymptotic normality of the split-and-conquer (SaC), the weighted distributed (WD), the debiased split-and-conquer (dSaC) and the debiased weighted distributed (dWD) estimators with respect to the number of data blocks \( K \). The dimension \( p_2 \) of the nuisance parameter \( \lambda_k \) is 10 and total sample size \( N = 2 \times 10^6 \).

In addition to the simulation experiments on the statistical properties of the estimators, the computation efficiency of the estimators was also evaluated. Table 3 reports the average CPU time per simulation run based on 500 replications of the five estimators for a range of \( K \) of the nuisance parameter for the logistic regression model with the total sample size \( N = 2 \times 10^6 \) and \( p_2 = 10 \). The computation speed of the dSaC and dWD estimators were relatively slower than those of the SaC, WD and Zhang’s SAVGM estimators. The WD estimator was quite fast, which means that the re-weighting used less computing time than the bias-reduction. In comparison, the dWD estimator was the slowest as a cost for attaining the best root mean squared error among the five estimators in all settings. It is observed in Table 3 that the overall computation time for each estimator first decreased and then increased as \( K \) became larger. The decrease in time was because of the benefit of the distributed computation, while the increase was due to the increase in the number of optimization associated with the statistical optimization performed as \( K \) got larger. However,
it is worth mentioning that these results did not account for the potential time expenditure in data communication among different data blocks.

Table 3: Average CPU time for each replication based on \( B = 500 \) replications for the split-and-conquer (SaC), the Zhang’s SAVGM, the weighted distributed (WD), the debiased split-and-conquer (dSaC) and the debiased weighted distributed (dWD) estimators for the logistic regression model with respect to \( K \). The dimension \( p_2 \) of the nuisance parameter \( \lambda_k \) is 10 and total sample size \( N = 2 \times 10^6 \)

6.2 Real data analysis

We report results from an empirical analysis of an airline’s on-time performance data to demonstrate the proposed weighted distributed estimation for massive data. We aim to quantify the association between flight departure delay and a set of covariates, the arrival delay of the previous flight of the same plane, the seasonal effects, and the weather conditions with a logistic regression model, based on data from the top 10 busiest airports in the United States in 2007. The flight data are available from https://community.amstat.org/jointscsg-section/dataexpo/dataexpo2009 and the weather data are obtained from https://cds.climate.copernicus.eu/. We segmented the full data of \( N = 2412782 \) according to the airports of departing flights and obtained 10 data segments. For each segment, we split it to data blocks of size \( n = 5000 \), while the residual data blocks were discarded, such that the total number of blocks \( K = 479 \).

We included seven covariates in the logistic regression: the arrival delay of the previous flight, the season (encoded by three dummy variables: spring (March-May), summer (June-August), autumn (September-November) with winter as the baseline, the near-surface air temperature and pressure, and the rain rate before the scheduled departure time. The coefficients of the three weather variables were treated as the common parameters while the remaining coefficients including the intercept were regarded as heterogeneous; see Section C.3 in the supplementary material for the justification. The estimated common parameters of the near-surface air pressure, temperature, and convective rain rate with 95\% confidence intervals using the weighted distributed estimator and the split-and-conquer estimator are shown in Figure 2. Both methods successfully identified a significant association between the three weather variables and the departure delay of a flight. Besides, the weighted distributed estimator reduced the lengths of the confidence intervals of the estimated common parameters compared with the split-and-conquer method. In particular, the confidence interval of the rain parameter was shortened by 19.1\%, while those of the other two common parameters
were shorted by 2.2% (pressure) and 2.9% (temperature), which justified the statistical efficiency of the weighted distributed estimator.

The data analysis demonstrated the feasibility of implementing the proposed weighted distributed estimation method for real-world distributed inference problems. With only one round of weighting to tackle the heterogeneity among the nuisance parameters, more efficient estimation can be obtained.

Figure 2: Estimated common parameters of the near surface air pressure, temperature and convective rain rate with 95% confidence intervals using the weighted distributed estimator and the split-and-conquer estimator

7. Discussion

This paper investigates distributed statistical optimization in the presence of heterogeneity among the data blocks. The weighted distributed estimator can improve the estimation efficiency of the split-and-conquer estimator for the common parameter. Two debiased estimators are proposed to allow for larger numbers of data blocks $K$. The statistical properties of the proposed estimators are shown to be advantageous over the split-and-conquer and SAVGM estimators. In particular, the
weighted distributed estimator performs well for smaller $K$ relative to $N$, and the debiased weighted distributed estimator that conducted both bias correction and weighting offers good estimation accuracy for large $K$.

An important issue for the distributed estimation is the size of $K$ relative to the full sample size $N$. Both the split-and-conquer and weighted distributed estimators require $K = o(N^{1/2})$ to preserve the the $N^{1/2}$ convergence rate. The debiased weighted distributed and debiased split-and-conquer estimators relax the restriction to $K = o(N^{2/3})$ without sacrificing the statistical efficiency.

Our finding that the heterogeneity requires separate weighting for better efficiency gain has implications beyond the current context. In particular, the proposed WD estimator can be extended to a multi-round procedure, where one can substitute the WD estimator back to the local loss functions, update the remaining local parameters, and then repeat the WD procedure. However, it may be shown that under the current M-estimation framework which is non-degenerate in the sense of Chen and Peng (2021), doing so could not lead to further gain in the efficiency beyond the WD estimator, as it suffices to achieve statistical efficiency with a one-round averaging as the WD. Nevertheless, it is of interest to explore further for the degenerate cases as the above statement may no longer be applicable.

The heterogeneous M-estimation framework in this work is related to the federated learning (McMahan et al. 2017), where one wants to minimize a federated risk function

$$M(\phi) = \sum_{k=1}^{K} w_k M_k(\phi),$$

where $M_k(X_k; \cdot)$ is the $k$-th client specific loss function, $M_k(\phi) = E_{P_k}(M_k(X_k; \phi))$ is the corresponding risk function, $\phi \in \mathbb{R}^{p_1}$ is the parameter of interest and $w_k$ is the pre-specified weight of the $k$-th client with a natural choice $w_k = 1/K$. The local distributions $\{P_k\}_{k=1}^{K}$ may be not identically distributed to reflect heterogeneity. In (17), only a shared parameter $\phi$ needs to be estimated, and the heterogeneity is hidden in the local loss and risk functions.

Our formulation is different from the federated risk function (17), where the $\{M_k\}_{k=1}^{K}$ are parameterized via the heterogeneous local parameters $\{\lambda_k\}_{k=1}^{K}$, leading to

$$M_k(X_k; \cdot) = M(X; \phi, \lambda_k)$$

for inference on $\phi$. Our finding that by actively weighting with respect to the heterogeneity as in the WD estimation can provide useful guideline for the selection of the weights $w_k$ in (17) of the federated learning.

Different from (17), the federated multi-task learning (Smith et al. 2017) is designed to tackle the heterogeneity in a distributed network, which fits separate local parameters $\{\phi_k\}_{k=1}^{K} \subset \mathbb{R}^{p_1}$ to different data blocks (tasks) through loss functions $\{\ell_k(\cdot, \cdot)\}_{k=1}^{K}$ and its general formulation is

$$\min_{\Phi, \Omega} \left\{ \sum_{k=1}^{K} \sum_{i=1}^{n_k} \ell_k(\phi_k^T X_{k,i}, Y_{k,i}) + \mathcal{R}(\Phi, \Omega) \right\},$$

where $\Phi$ is the matrix with $\{\phi_k\}_{k=1}^{K}$ as column vectors, $\Omega \in \mathbb{R}^{K \times K}$ and $\mathcal{R}(\cdot, \cdot)$ measures the extent of the heterogeneity among different data blocks. Choices of $\mathcal{R}(\cdot, \cdot)$ include the bi-convex function $\mathcal{R}(\Phi, \Omega) = \delta_1 \text{trace}(\Phi \Omega \Phi^T) + \delta_2 \|\Phi\|_F^2$ for $\delta_1, \delta_2 > 0$ and $\Omega = I_{K \times K} - (1/K)1_K 1_K^T$ such
that \( \text{trace}(\Phi \Omega \Phi^T) = \sum_{k=1}^{K} \| \phi_k - \bar{\phi}_K \|^2_2 \) where \( \bar{\phi}_K = (1/K) \sum_{k=1}^{K} \phi_k \), which leads to the mean-regularized multi-task learning (Evgeniou and Pontil, 2004) with \( R \) conducting regularization on each local model. Similar regularization formulations have also been applied in personalized federated learning (T. Dinh et al., 2020; Li et al., 2021). Other than regularization methods, Marfoq et al. (2021) proposed a clustering-based method, where the \( \{P_k\}_{k=1}^{K} \) are assumed to be sampled from a mixture of \( S \) \( (S \ll K) \) underlying distributions. It is also noted that although federated multi-task learning assumes different parameters \( \{\phi_k\}_{k=1}^{K} \) over the data blocks, it regularizes them toward a common one. In contrast, we assume there is a common parameter \( \phi \) shared by the distributions. By doing so, we can clarify the source of heterogeneity \( \{\lambda_k\}_{k=1}^{K} \) and homogeneity \( \phi \) instead of putting an equal treatment on all the dimensions of the parameter and focusing on the statistical inference of the common parameter.

Acknowledgments

The authors would like to thank the two anonymous referees, the Associate Editor, and the Editor for their thoughtful comments and suggestions, which have improved the presentation of the paper. This research is funded by National Natural Science Foundation of China Grants 12071013 and 12026607.
The Appendix is organized as follows. Section A provides derivations of the formulas given in the main text. Section B contains detailed proofs of the theoretical results. More simulation results and details about the real data analysis are reported in Section C.

Appendix A. Derivation of formulas

A.1 Expansion of the full sample estimator \( \hat{\phi}_{\text{full}} \)

By integral form of Taylor’s expansion around the true value \( \theta^* \), we have

\[
0_{p \times 1} = \Psi_N(X; \hat{\phi}_{\text{full}}, \hat{\lambda}_{1,\text{full}}, ..., \hat{\lambda}_{K,\text{full}})
= \Psi_N(X; \theta^*) + J(\theta^*)(\hat{\phi}_{\text{full}} - \theta^*) + (\nabla \Psi_N(X; \theta^*) - J(\theta^*))(\hat{\phi}_{\text{full}} - \theta^*)
+ \left\{ \int_0^1 \nabla \Psi_N(X; \theta^*) + t(\hat{\phi}_{\text{full}} - \theta^*) \right\} dt - \nabla \Psi_N(X; \theta^*) \right\}
\]

where \( J(\theta) = E(\nabla \Psi_N(X; \theta)) \). Then, inverting the above leads to

\[
\hat{\phi}_{\text{full}} - \theta^* = -J(\theta^*)^{-1} \Psi_N(X; \theta^*) + R_{N1} + R_{N2},
\]

where \( R_{N1} = -J(\theta^*)^{-1} \{ \nabla \Psi_N(X; \theta^*) - J(\theta^*) \} \right\}(\hat{\phi}_{\text{full}} - \theta^*) \) and \( R_{N2} = -J(\theta^*)^{-1} \left\{ \int_0^1 \nabla \Psi_N(X; \theta^*) + t(\hat{\phi}_{\text{full}} - \theta^*) \right\} dt - \nabla \Psi_N(X; \theta^*) \} \right\}(\hat{\phi}_{\text{full}} - \theta^*) \) are both higher-order remainder terms. Since \( J(\theta) \) has the following form

\[
J(\theta) = 
\begin{pmatrix}
\sum_{k=1}^K n_k \Psi_\phi^\lambda(\theta_k) & n_1 \Psi_\phi^\lambda(\theta_1) & ... & n_K \Psi_\phi^\lambda(\theta_K) \\
n_1 \Psi_\phi^\lambda(\theta_1) & n_1 \Psi_\phi^\lambda(\theta_1) & 0 & 0 \\
... & 0 & ... & 0 \\
n_K \Psi_\phi^\lambda(\theta_K) & 0 & 0 & n_K \Psi_\phi^\lambda(\theta_K)
\end{pmatrix},
\]

then the right bottom part of \( J(\theta) \) is a block diagonal matrix, whose inverse is at hand. Thus we can see \( J(\theta) \) as a \( 2 \times 2 \) block matrix and directly apply the block matrix inverse formula (Lu and Shiou, 2002). Thus from (20) we have

\[
\hat{\phi}_{\text{full}} - \theta^* = -\left( \sum_{k=1}^K (n_k/N) J_{\phi(\theta_k)} \right)^{-1} \left( 1/N \right) \left( \sum_{k=1}^K n_k \sum_{i=1}^{n_k} S_\phi(X_{k,i}; \theta_k^*) \right) + o_p(N^{-1/2}).
\]

A.2 Errors-in-variables model

We first give a derivation of the objective function from the perspective of statistical optimization. As we will see, the derived objective is exactly the same as that when we do orthogonal regression or “Deming’s regression” (Carroll and Ruppert, 1996). Consider the conditional likelihood of \( (X_{k,i}, Y_{k,i}) \) given \( Z_{k,i} \) in block \( k \)

\[
f(\{X_{k,i}, Y_{k,i}\}|\{Z_{k,i}\}, \theta_k) = \prod_{i=1}^{n_k} f_1(X_{k,i}|Z_{k,i}) f_2(Y_{k,i}|Z_{k,i})
= (1/2\pi\sigma^2)^n \prod_{i=1}^{n_k} \exp \left( -\frac{1}{2\sigma^2} \left[ \left( X_{k,i}^2 + (Y_{k,i} - \phi)^2 \right) - 2Z_{k,i}(X_{k,i} + \lambda_k(Y_{k,i} - \phi)) + (1 + \lambda_k^2)Z_{k,i}^2 \right] \right).
\]
By the factorization theorem, $X_{k,i} + \lambda_k(Y_{k,i} - \phi)$ is a sufficient statistic for $Z_{k,i}$ if $\theta_k = (\phi, \lambda_k)$ is assumed to be known. And $X_{k,i} + 2\lambda_k(Y_{k,i} - \phi)|Z_{k,i} \sim \mathcal{N}(1 + \lambda_k^2)Z_{k,i}, (1 + \lambda_k^2)\sigma^2)$. Then, the above conditional likelihood can be factorized as

$$f(\{X_{k,i}\}, \{Y_{k,i}\}|\{Z_{k,i}\}, \theta_k) = \left(\frac{1 + \lambda_k^2}{\sqrt{2\pi}\sigma}\right)^n \prod_{i=1}^n \exp\left(-\frac{1}{2\sigma^2(1 + \lambda_k^2)}(\lambda_k X_{k,i} - (Y_{k,i} - \phi))^2\right) h(X_{k,i} + \lambda_k(Y_{k,i} - \phi)|Z_{k,i}),$$

where $h(s_i|z_i)$ is the conditional density of $\mathcal{N}((1 + \lambda_k^2)z_i, (1 + \lambda_k^2)\sigma^2)$. Since $\{Z_{k,i}\}_{i=1}^n$ are not observable, we discard the factor $h$ and construct the estimator based on the first part of the factorization, which is denoted as $\hat{f}(\{X_{k,i}\}, \{Y_{k,i}\}|\{Z_{k,i}\}, \theta_k)$. Differentiate $\log \hat{f}(\{X_{k,i}\}, \{Y_{k,i}\}|\{Z_{k,i}\}, \theta_k)$ with respect to $\theta_k = (\phi, \lambda_k)^T$, we obtain

$$\frac{\partial}{\partial \phi} \log \hat{f}(\{X_{k,i}\}, \{Y_{k,i}\}|\{Z_{k,i}\}, \theta_k) = -\frac{1}{\sigma^2(1 + \lambda_k^2)} \sum_{i=1}^n (\lambda_k X_{k,i} - (Y_{k,i} - \phi)) \quad \text{and}$$

$$\frac{\partial}{\partial \lambda_k} \log \hat{f}(\{X_{k,i}\}, \{Y_{k,i}\}|\{Z_{k,i}\}, \theta_k) = \frac{n \lambda_k}{1 + \lambda_k^2} + \sum_{i=1}^n \frac{\lambda_k}{\sigma^2(1 + \lambda_k^2)^2} (\lambda_k X_{k,i} - (Y_{k,i} - \phi))^2$$

$$- \sum_{i=1}^n \frac{X_{k,i}}{\sigma^2(1 + \lambda_k^2)} (\lambda_k X_{k,i} - (Y_{k,i} - \phi)).$$

However, $E\left(\nabla \hat{f}(\{X_{k,i}\}, \{Y_{k,i}\}|\{Z_{k,i}\}, \theta_k^*)\right) = (0, n\lambda_k^*/(1 + \lambda_k^2))^T \neq 0_{2 \times 1}$, thus a correction term should be added to construct an appropriate objective function which satisfies the standard first-order condition in statistical optimization framework:

$$M_{n,k}(\{X_{k,i}\}, \{Y_{k,i}\}|\{Z_{k,i}\}, \theta_k) = -\log \hat{f}(\{X_{k,i}\}, \{Y_{k,i}\}|\{Z_{k,i}\}, \theta_k) + \frac{n}{2} \log(1 + \lambda_k^2)$$

$$= \frac{1}{2\sigma^2(1 + \lambda_k^2)} \sum_{i=1}^n (\lambda_k X_{k,i} - (Y_{k,i} - \phi))^2 + C(\sigma),$$

where $C(\sigma) = n\log(\sqrt{2\pi}\sigma)$ is an absolute constant so we also discard it. The corresponding $M$-function is

$$M(X_k, \theta_k) = \frac{1}{2\sigma^2(1 + \lambda_k^2)} (\lambda_k X_k - (Y_k - \phi))^2.$$(22)  

Below we check the identification of the true parameter under this objective function. We can directly solve the population level first-order conditions (FOC) using $E(\nabla M(X_k, Y_k|Z_k, \theta_k)) = 0_{2 \times 1}$, which are given as

$$0_{2 \times 1} = \left(1 + \lambda_k^2\right)\left((\lambda_k - \lambda_k^*)E(Z_k) - (\phi^* - \phi)\right)$$

$$+ \left((\lambda_k \lambda_k^* + 1)(\lambda_k - \lambda_k^*)E(Z_k^2) - \lambda_k^*E(Z_k)^2 - \lambda_k^*(\phi - \phi^*)^2 + (\phi - \phi^*)(1 + 2\lambda_k \lambda_k^* - \lambda_k^2)E(Z_k)\right).$$

To solve the above set of equations, we consider the two scenarios. When $E(Z_k) = 0$, from the first equation we obtain $\phi = \phi^*$, then the second equation reduces to $C(\lambda_k \lambda_k^* + 1)(\lambda_k - \lambda_k^*)E(Z_k^2) - \lambda_k^*E(Z_k)^2$.
\( \lambda_k^* E(Z_k^2) = 0 \). Since we have assumed \( \lambda_k, \lambda_k^* > 0 \), we must have \( \lambda_k = \lambda_k^* \). When \( E(Z_k) \neq 0 \), if \( \lambda_k \neq \lambda_k^* \) we would obtain \( E(Z_k) = (\phi^* - \phi)/(\lambda_k - \lambda_k^*) \). Plugging it into the second equation of (23) and we can obtain

\[
\frac{(1 + \lambda_k \lambda_k^*)}{\sigma^2(1 + \lambda_k^2)^2(\lambda_k - \lambda_k^*)} (\lambda_k - \lambda_k^*)^2 E(Z_k^2) - (\phi - \phi^*)^2 = 0,
\]

which is impossible unless \( Z_k \) is degenerate, namely \( Z_k = (\phi^* - \phi)(\lambda_k - \lambda_k^*) \) with probability one. This leads to a contradiction. Thus we must have \( \lambda_k = \lambda_k^* \). Again from the first equation of (23) we will obtain that \( \phi = \phi^* \). In summary, \( E(\nabla M(X_k, Y_k|Z_k, \theta_k)) = 0_{2 \times 1} \) if and only if \( \theta_k = \theta_k^* \).

To give an explicit form of asymptotic variance of the estimator obtained from the \( M \)-function (22), we can directly calculate the following two terms:

\[
E(\nabla^2 M(X_k, Y_k|Z_k; \theta_k^*)) = E \left( \frac{X_k}{\sigma^2(1 + \lambda_k^2)} - \frac{3\lambda_k^*(\lambda_k^* - \phi^*)}{\sigma^2(1 + \lambda_k^2)^2} \right) = \frac{X_k}{\sigma^2(1 + \lambda_k^2)} - \frac{3\lambda_k^*(\lambda_k^* - \phi^*)}{\sigma^2(1 + \lambda_k^2)^2}.
\]

Thus we have

\[
J_{\phi|\lambda}(\theta_k^*) = \frac{1}{\sigma^2(1 + \lambda_k^2)} (1 - \frac{E(Z_k)^2}{E(Z_k)^2}) = \frac{1}{\sigma^2(1 + \lambda_k^2)} \frac{\text{Var}(Z_k)}{E(Z_k)^2},
\]

and

\[
\text{Var}(S_{\phi}) = \left(1 - \frac{E(Z_k)}{E(Z_k)^2}\right) \frac{1}{\sigma^2(1 + \lambda_k^2)} \left( \frac{1}{E(Z_k)} E(Z_k)^2 + \frac{\sigma^2}{1 + \lambda_k^2} \right) = \frac{1}{\sigma^2(1 + \lambda_k^2)} \frac{\text{Var}(Z_k)}{E(Z_k)^2} + \frac{\sigma^2}{1 + \lambda_k^2} \frac{(E(Z_k)^2)}{E(Z_k)^2},
\]

which leads to the Equation (8) in the main text.

### A.3 Equivalent variance minimization formulations of the weighted estimators

For simplicity, we assume that \( n_1 = n_2 = \cdots = n_K = n \). We claim that the following two formulations of the variance minimization problem have identical solution.

**Formulation 1: Trace Operator**

\[
\text{Minimize } \text{trace} \left( \sum_{k=1}^{K} W_k H_k W_k^T \right), \quad \text{s.t. } \sum_{k=1}^{K} W_k = I_{p_1}.
\]

**Formulation 2: Frobenius Norm**

\[
\text{Minimize } \| \sum_{k=1}^{K} W_k H_k W_k^T \|_F, \quad \text{s.t. } \sum_{k=1}^{K} W_k = I_{p_1}.
\]
Proof We solve the problem (24) first. The Lagrangian of this problem is

$$L_1 = \text{trace} \left( \sum_{k=1}^{K} W_k H_k W_k^T \right) + \langle \Lambda_1, \sum_{k=1}^{K} W_k - I_p \rangle,$$

where $\Lambda_1 \in \mathbb{R}^{p_1 \times p_1}$ is the corresponding Lagrangian multiplier. If we take derivative of $L_1$ w.r.t. $W_k$ we can obtain $2W_k H_k + \Lambda_1 = 0$, $k = 1, 2, \ldots, K$. Then $W_k = -\frac{1}{2} \Lambda_1 H_k^{-1}$. Using the constraint $\sum_{k=1}^{K} W_k = I_p$, we can obtain $\Lambda_1^* = -2(\sum_{s=1}^{K} A_s^{-1})^{-1}$ and $W_k^* = (\sum_{s=1}^{K} A_s^{-1})^{-1} A_k^{-1}$. Now we turn to solve the problem (25). Equivalently we can minimize the square of the Frobenius norm, and the corresponding Lagrangian is

$$L_2 = \| \sum_{k=1}^{K} W_k H_k W_k^T \|_F^2 + \langle \Lambda_2, \sum_{k=1}^{K} W_k - I_p \rangle.$$

Taking derivative w.r.t. $W_k$ we can obtain $4(\sum_{s=1}^{K} W_s A_s W_s^T) W_k A_k + \Lambda_2 = 0$. Now we can use the constraint $\sum_{k=1}^{K} W_k = I_p$, and get $\Lambda_2^* = -4(\sum_{s=1}^{K} W_s A_s W_s^T)(\sum_{s=1}^{K} A_s^{-1})^{-1}$ and $W_k^* = (\sum_{s=1}^{K} A_s^{-1})^{-1} A_k^{-1}$. $lacksquare$

A.4 Second-order Bartlett’s indentity under QMLE

For the quasi maximum likelihood estimation (QMLE), we only check that the second order Bartlett’s identity holds for independent observations. Suppose that the components of the response vector $Y$ are independent with mean vector $\mu$ and covariance matrix $\sigma^2 V(\mu)$, where $\sigma^2$ maybe unknown and $V(\mu)$ is a matrix of known functions. It is assumed that the parameters of interest, $\theta$, is a function of $\mu$. By independence of the components of $Y$ and the physical mechanism plausibility, it is reasonable to assume further that $V_i(\mu)$ depends on $\mu$ only through $\mu_i$, which implies that

$$V(\mu) = \text{diag}\{V_1(\mu_1), V_2(\mu_2), \ldots, V_n(\mu_n)\}.$$

For a single observation $Y$, we can construct the score function as $U = u(\mu; Y) = (Y - \mu) / (\sigma^2 V(\mu))$. Then the corresponding objective function can be defined as

$$Q(\mu; y) = \int_{y}^{\mu} \frac{y - t}{\sigma^2 V(t)} dt,$$

which behaves like a negative log-likelihood: $E_{\nu}(\nabla_{\mu} Q) = 0$, $\text{Var}(\nabla_{\mu} Q) = E_{\nu}(\nabla_{\mu}^2 Q) = 1 / \{\sigma^2 V(\mu)\}$. We refer to $Q(\mu; y)$ as the negative quasi-likelihood (McCullagh, 1983), or more precisely the negative log quasi-likelihood for $\mu$ based on data $y$. By independence, the negative quasi-likelihood for the complete data is the sum of the individual contributions: $Q(\mu; y) = \sum_{i=1}^{n} Q(\mu_i; y_i)$. The quasi-likelihood estimating equations for the regression parameters $\theta$, obtained by differentiating $Q(\mu; y)$, can be written in the form $U(\hat{\theta}) = 0$, where $U(\theta) = -DV^{-1}(Y - \mu) / \sigma^2$ is called the quasi-score function. The components of $D$, of order $n \times p$, are $D_{\nu i} = \partial \mu_i / \partial \theta_{\nu}$, the derivatives of $\mu_i(\theta)$ with respect to the parameters. Suppose the true parameters are $\theta^*$ and $\mu^*$, then by the zero-mean of $U(\theta^*)$, we have

$$\text{CoV}\{U(\theta^*)\} = E\{U(\theta^*)U(\theta^*)^T\} = D^T V^{-1} D / \sigma^2$$

and

$$E\left( \frac{\partial U}{\partial \theta^T} (\theta^*) \right) = E\{D^T V^{-1} \partial \mu / \partial \theta^T / \sigma^2 + \partial D^T V^{-1} Y - \mu^* / \sigma^2 \} = D^T V^{-1} D / \sigma^2.$$
A.5 Generalized second-order Bartlett’s identity for parametric regression

Suppose that we observe a random sample \((X_1, Y_1), (X_2, Y_2), \ldots, (X_n, Y_n)\), which follows

\[ Y = f_\theta(X) + e, \quad E(e|X) = 0, \quad \text{Var}(e|X) = \sigma^2(X), \quad X \sim p(x). \]

Then the objective function for the least square estimation is

\[ M(Z, \theta) = (Y - f_\theta(X))^2 \]

with \(Z = (X, Y)\). Note that

\[ E(M(Z, \theta)) = E(f_\theta(X) - f_\theta(X))^2 + Ee^2 \approx E(M(Z, \theta^*)) + E((\theta - \theta^*)^T \nabla f_\theta(X))^2, \quad (27) \]

which suggests that

\[ \nabla^2_\theta M(\theta^*) = 2E \nabla f_\theta(X) \nabla f_\theta(X)^T \]

where \(M(\theta) = EM(Z, \theta)\). For the approximation \((27)\), see van der Vaart (1999). If we assume the independence between \(e\) and \(X\), which implies \(\text{Var}(e) = \sigma^2\), then

\[ E(M(Z, \theta^*)^T M(Z, \theta^*)) = 4\sigma^2 E(\nabla f_\theta(X) \nabla f_\theta(X)^T) \]

with the multiplicative factor \(\gamma\) for the generalized second-order Bartlett’s identity being \(4\sigma^2\).

A.6 GMM formulation of the full sample statistical optimization under heterogeneity

It is noted that \(W_0\) admits the following form

\[ W_0 = \begin{pmatrix}
\text{Var} \{\psi_{\theta_1}(X_{1,1}; \phi^*, \lambda_1^*)\}^{-1} & 0 & \cdots & 0 \\
0 & \text{Var} \{\psi_{\theta_2}(X_{2,1}; \phi^*, \lambda_2^*)\}^{-1} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \text{Var} \{\psi_{\theta_K}(X_{K,1}; \phi^*, \lambda_K^*)\}^{-1}
\end{pmatrix} \]

Thus, \(W_0\) is a block diagonal matrix. Also note that

\[ G_0^T = E(\frac{\partial^2 T(\theta^*\theta)}{\partial \theta \partial \theta}) \]

\[ = E\begin{pmatrix}
\psi_{\theta}(X_{1,i}; \phi^*, \lambda_1^*) & \psi_{\theta}(X_{1,i}; \phi^*, \lambda_1^*) & \cdots & \psi_{\theta}(X_{1,i}; \phi^*, \lambda_K^*) \\
0 & \psi_{\theta}(X_{2,i}; \phi^*, \lambda_2^*) & \cdots & \psi_{\theta}(X_{2,i}; \phi^*, \lambda_K^*) \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \psi_{\theta}(X_{K,i}; \phi^*, \lambda_K^*)
\end{pmatrix} \]

then the asymptotic variance of the GMM estimator (Hansen, 1982) is

\[\text{Asy} Var(\hat{\theta}_{\text{GMM}}) = (G_0^T W_0 G_0)^{-1}\]

and has the following form:

\[
\begin{pmatrix}
\sum_{k=1}^{K} n_k D\Psi_{\phi}(\theta_k^*)^T \Sigma_{S,K}^{-1} D\Psi_{\phi}(\theta_k) & n_1 D\Psi_{\phi}(\theta_1^*)^T \Sigma_{S,1}^{-1} D\Psi_{\phi}(\theta_1^*) & \cdots & n_K D\Psi_{\phi}(\theta_K^*)^T \Sigma_{S,K}^{-1} D\Psi_{\phi}(\theta_K^*) \\
n_1 D\Psi_{\lambda}(\theta_1^*)^T \Sigma_{S,1}^{-1} D\Psi_{\phi}(\theta_1^*) & n_1 D\Psi_{\lambda}(\theta_1^*)^T \Sigma_{S,1}^{-1} D\Psi_{\lambda}(\theta_1^*) & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
n_K D\Psi_{\lambda}(\theta_K^*)^T \Sigma_{S,K}^{-1} D\Psi_{\phi}(\theta_K^*) & 0 & \cdots & 0
\end{pmatrix}^{-1},
\]

where

\[D\Psi_{\phi}(\theta_k)^T = \begin{pmatrix} \psi_{\phi}(\theta_k) & \Psi_{\phi}(\theta_k) \end{pmatrix}, \quad D\Psi_{\lambda}(\theta_k)^T = \begin{pmatrix} \psi_{\lambda}(\theta_k) & \Psi_{\lambda}(\theta_k) \end{pmatrix}\]

and \(\Sigma_{S,K} = \text{Var} \{\psi_{\theta_k}(X_{K,1}; \phi^*, \lambda_k^*)\}\).
By the inversion of block matrix, approximately \( \text{Var}(\hat{\phi}_{\text{GMM}})^{-1} \) has the following form:

\[
\sum_{k=1}^{K} n_k \left\{ D\Psi_\phi(\theta_k^*)^T \Sigma_{S,k}^{-1} D\Psi_\phi(\theta_k^*) - D\Psi_\phi(\theta_k^*)^T \Sigma_{S,k}^{-1} D\Psi_\lambda(\theta_k^*) \left( D\Psi_\lambda(\theta_k^*)^T \Sigma_{S,k}^{-1} D\Psi_\lambda(\theta_k^*) \right)^{-1} D\Psi_\lambda(\theta_k^*)^T \Sigma_{S,k}^{-1} D\Psi_\phi(\theta_k^*) \right\}.
\]

If we denote the elements in the above summation as \( n_k U_k \), then it is straightforward to verify that

\[
\left( U_k^{-1} * * \right) = \left\{ \left( D\Psi_\phi(\theta_k^*)^T D\Psi_\lambda(\theta_k^*) \right) \Sigma_{S,k} \left( D\Psi_\phi(\theta_k^*) D\Psi_\lambda(\theta_k^*) \right)^{-1} \right\},
\]

namely, the inverse of \( U_k \) is the left top part of the inverse of a bigger matrix in the RHS of the above equation, from which we are able to obtain the simplified expression of \( U_k \):

\[
U_k = \left\{ J_{\phi|\lambda}^{-1} \left( I_{p_1 \times p_1} - \Psi_\lambda^\phi(\theta_k^*) \Psi_\lambda^\lambda(\theta_k^*)^{-1} \right) \Sigma_{S,k} \left( -\Psi_\lambda^\phi(\theta_k^*)^{-1} \Psi_\lambda^\lambda(\theta_k^*) \right) J_{\phi|\lambda}^{-1} \right\}^{-1} = J_{\phi|\lambda} \Sigma_{S,k}^{-1} J_{\phi|\lambda}.
\]

Now we conclude that \( \text{Var}(\hat{\phi}_{\text{GMM}}) \approx \left( \sum_{k=1}^{K} J_{\phi|\lambda} \Sigma_{S,k}^{-1} J_{\phi|\lambda} \right)^{-1} \), which is the same as that of the WD estimator \( \hat{\phi}_{\text{WD}} \).

### A.7 Lipschitz continuity of the outer product of the gradient in logistic regression model

First we define the logit function \( \text{logit}(a) = \exp(a)/(1 + \exp(a)) \) for \( a \in \mathbb{R} \). Then the logistic regression model can be defined as \( P(Y = 1|X) = \text{logit}(X^T \beta^*) \), where \( X, \beta^* \in \mathbb{R}^p \). If we define the objective \( M \) as \( M(z, \beta) = -y \log(\text{logit}(x^T \beta)) + (y - 1) \log(1 - \text{logit}(x^T \beta)) \), where \( z = (y, x) \), then the outer product of gradient, denoted as \( f(z, \beta) \), is \( f(z, \beta) = (y - \text{logit}(x^T \beta))^2 x x^T \). Now we have

\[
\| f(z, \beta_1) - f(z, \beta_2) \|_2 = \| x (x^T (2y - \text{logit}(x^T \beta_1) - \text{logit}(x^T \beta_2))(\text{logit}(x^T \beta_1) - \text{logit}(x^T \beta_2)) \|_2 \\
= \| x (x^T (2y - \text{logit}(x^T \beta_1) - \text{logit}(x^T \beta_2))(1 - \text{logit}(\xi)) \text{logit}(\xi) x (\beta_1 - \beta_2) \|_2 \\
\leq \| x \|_2^3 \| \beta_1 - \beta_2 \|_2,
\]

where the second equality comes from an application of the mean value theorem.

### A.8 Asymptotic efficiency comparison of \( \hat{\lambda}_k \) and \( \hat{\lambda}_k^{(2)} \)

**Theorem 9** Under the conditions required in Theorem 4, if \( K \to \infty \), then for the updated estimator \( \hat{\lambda}_k^{(2)} \), we have that

\[
\sqrt{n_k} (\hat{\lambda}_k^{(2)} - \lambda_k^*) \xrightarrow{d} \mathcal{N}(0, \Psi_\lambda^\phi(\theta_k^*)^{-1} E\psi(X, \beta_k^*) \psi(X, \beta_k^*)^T \Psi_\lambda^\phi(\theta_k^*)^{-1}). \tag{28}
\]
Hence, the asymptotic distribution of $\hat{\lambda}_k^{(2)}$ is the same as that of the estimator of $\lambda_k^*$ obtained when the common parameter $\phi^*$ is known. It is noted that the joint asymptotic distribution for the estimator $\hat{\theta}_k = (\hat{\phi}_k^T, \hat{\lambda}_k^T)^T$ is

$$
\sqrt{n_k}(\hat{\theta}_k - \theta_k^*) \xrightarrow{d} \mathcal{N}(0, J_k(\theta_k^*)^{-1}E\psi_{\theta_k}(X_{k,1}; \theta_k^*)\psi_{\theta_k}(X_{k,1}; \theta_k^*)^T J_k(\theta_k^*)^{-1}),
$$

which leads to

$$
\sqrt{n_k}(\hat{\lambda}_k - \lambda_k^*) \xrightarrow{d} \mathcal{N}(0, J_{\lambda}(\theta_k^*)^{-1}\text{Var}(S_{\phi}(X_{k,1}; \theta_k^*))J_{\lambda}(\theta_k^*)^{-1}). \tag{29}
$$

There is not a definite order on the relative efficiency between $\hat{\lambda}_k$ and $\hat{\lambda}_k^{(2)}$ by comparing the two asymptotic variances in (28) and (29), suggesting it would depend on the specific $M$ function and the model setting. For general statistical optimization, a known nuisance parameter (here $\phi^*$) does not necessarily improve the efficiency of a parameter of interest Yuan and Jennrich (2000); Henmi and Eguchi (2004), which is the case for the current setting. Consider again the errors-in-variables model where it can be shown that

$$
\text{Var}(\hat{\lambda}_k) \approx \frac{\sigma^4}{(\text{Var}(Z_k))^2 n_k} \quad \text{and} \quad \text{Var}(\hat{\lambda}_k) \approx \left(\frac{\sigma^4}{(E(Z_k^2))^2} + \frac{\sigma^2(1 + \lambda_k^2)}{E(Z_k^2)}\right) \frac{1}{n_k}.
$$

When $E(Z_k) = 0$, i.e. $\text{Var}(Z_k) = E(Z_k^2)$, the updated estimator $\hat{\lambda}_k^{(2)}$ is more efficient, and the efficiency gain gets large as $\lambda_k^2$ increases. However, if $E(Z_k)$ has a large absolute magnitude, $\hat{\lambda}_k$ can be more efficient than $\hat{\lambda}_k^{(2)}$. Moreover, the requirement in Theorem 9 that $K \to \infty$ is to obtain a succinct asymptotic variance of $\hat{\lambda}_k^{(2)}$. The above conclusion does not change for the fixed $K$ case. Consider block 1, we assume $\hat{\lambda}_1^{(2)} \xrightarrow{p} \lambda_1^*$ and $\hat{\phi}_1^{\text{WD}}$ is $\sqrt{n_1}$-consistent (detailed proofs of both claims are available in the next section). Then by Theorem 1 in Yuan and Jennrich (2000), if $\sqrt{n_1}\left(\frac{1}{n_1} \sum_{i=1}^{n_1} \psi_1(X_{1,i}; \theta_1^*) + \tilde{\Psi}_1^{\phi}(\theta_1^*) \tilde{\phi}_1^{\text{WD}} - \phi^*)\right) \xrightarrow{d} \mathcal{N}(0, \Omega)$, we will have $\sqrt{n_1}(\hat{\lambda}_1^{(2)} - \lambda_1^*) \xrightarrow{d} \mathcal{N}(0, \Omega)$ where $\Omega = \tilde{\Psi}_1^{\phi}(\theta_1^*)^{-1}Q\tilde{\Psi}_1^{\phi}(\theta_1^*)^{-1}$. Denote $T_{n,K} = \sqrt{n_1}\tilde{\Psi}_1^{\phi}(\theta_1^*)^{-1}\left(\frac{1}{n_1} \sum_{i=1}^{n_1} \psi_1(X_{1,i}; \theta_1^*) + \tilde{\Psi}_1^{\phi}(\theta_1^*) \tilde{\phi}_1^{\text{WD}} - \phi^*)\right)$, then $T_{n,K}$ should have the same asymptotic distribution as $\sqrt{n_1}(\hat{\lambda}_1^{(2)} - \lambda_1^*)$. So, we study the limiting behavior of $T_{n,K}$ for simplicity. Consider the homogeneous scenario as a special case when $\theta_1^* = \theta_2^* = \cdots = \theta_K^*$, $n_1 = n_2 = \cdots = n_K = n$, then the optimal weights are $W_1^* = W_2^* = \cdots = W_K^* = \frac{1}{K}I_{p_1 \times p_1}$. Now we have

$$
T_{n,K} = \frac{1}{\sqrt{n}}\tilde{\Psi}_1^{\phi}(\theta_1^*)^{-1}\left(\sum_{i=1}^{n_1} \psi_1(X_{1,i}; \theta_1^*) - \tilde{\Psi}_1^{\phi}(\theta_1^*) \sum_{k=1}^{K} \frac{1}{K} (\tilde{\phi}_k - \phi^*)\right)
$$

$$
= \frac{1}{\sqrt{n}}\tilde{\Psi}_1^{\phi}(\theta_1^*)^{-1}\left(\sum_{i=1}^{n_1} \psi_1(X_{1,i}; \theta_1^*) - \tilde{\Psi}_1^{\phi}(\theta_1^*) \left(\frac{1}{K} \sum_{k=1}^{K} J_{\phi,1}(S_{\phi}(X_{k,i}; \theta_1^*)\right) + o_p(1)\right)
$$

$$
= \left(1 - \frac{1}{K}\tilde{\Psi}_1^{\phi}(\theta_1^*)^{-1}\tilde{\Psi}_1^{\phi}(\theta_1^*) \right) \frac{1}{\sqrt{n}} I_{p_2 \times p_2} \nabla^2 M_1(\theta_1^*)^{-1} \frac{1}{\sqrt{n}} \sum_{i=1}^{n_1} \left(\tilde{\psi}_1(X_{1,i}; \theta_1^*)\right) - \tilde{\Psi}_1^{\phi}(\theta_1^*)^{-1}\tilde{\Psi}_1^{\phi}(\theta_1^*) \frac{1}{\sqrt{n}} \sum_{k=2}^{K} \sum_{i=1}^{n_1} J_{\phi,1}(S_{\phi}(X_{k,i}; \theta_1^*)\right) + o_p(1) \overset{\Delta}{=} T_{n,K}^{(1)} + o_p(1).
$$
We can verify that \( \text{Var}(\theta_{n,k}^{(1)}) = (1 - \frac{1}{K})\Psi_1^J(\theta_1^*)^{-1}\text{Var}(\psi\lambda(X_{1,1};\theta_1^*))\Psi_0(\theta_1^*)^{-1} + \frac{n}{K}\text{Var}(\hat{\lambda}_1) \), or equivalently, \( \text{Var}(\hat{\lambda}_1^{(2)}) \approx (1 - \frac{1}{K})\Psi_1^J(\theta_1^*)^{-1}\text{Var}(\psi\lambda(X_{1,1};\theta_1^*))\Psi_0(\theta_1^*)^{-1} + \frac{n}{K}\text{Var}(\hat{\lambda}_1) \). Thus \( \text{Var}(\hat{\lambda}_1^{(2)}) \leq \text{Var}(\hat{\lambda}_1) \) if and only if
\[
\Psi_1^J(\theta_1^*)^{-1}\text{Var}(\psi\lambda(X_{1,1},\theta_1^*))\Psi_0(\theta_1^*)^{-1}/n \leq \text{Var}(\hat{\lambda}_1).
\]

The LHS of inequality (30) is the asymptotic variance of the estimator of \( \lambda_1^* \) if \( \phi_1^* \) is known and RHS is the asymptotic variance of estimator of \( \lambda_1^* \) when we jointly estimate \( (\phi_1^T, \lambda_1^T)^T \). Henmi and Eguchi (2004) showed that the inequality does not always hold for general statistical optimization problem and derived a sufficient condition under which a known nuisance parameter \( (\phi_1^*) \) will lead to a bigger asymptotic variance of the estimator of the parameter of interest \( (\lambda_1^*) \).

A.9 Comparison with a one-step estimator

Huang and Huo (2019), also under the same homogeneous setting, considered to utilize the second order information of the \( M \)-function to allow for a larger \( K \). They proposed a one-step estimator which aggregates the local Hessian matrices and gradients and performs a single Newton-Raphson updating. The estimator, denoted as \( \hat{\theta}^{(1)} \), has a MSE upper bound
\[
E\left(\|\hat{\theta}^{(1)} - \theta_1^*\|^2\right) \leq 2E\left(\|\nabla_{\theta_1} \Psi_0(\theta_1^*)^{-1}\psi_{\theta_1}(X_{1,1};\theta_1^*)\|^2\right)/nK + C_1/n^2 + C_2/n^4.
\]

Thus, this method allows for \( K = o(n^3) \), while still preserves the \( O(N^{-1}) \) convergence rate. The price of this procedure is one extra round of transmission of the local Hessians and gradients. To mitigate the communication burden, they considered to use only one local Hessian matrix instead of the averaged one. Let \( \hat{\theta}_{LH}^{(1)} \) be the estimator. They showed that
\[
E\left(\|\hat{\theta}_{LH}^{(1)} - \theta_1^*\|^2\right) \leq 2E\left(\|\nabla_{\theta_1} \Psi_0(\theta_1^*)^{-1}\psi_{\theta_1}(X_{1,1};\theta_1^*)\|^2\right)/nK + C_1/n^2K + C_2/n^3,
\]
which is similar to the MSE bound of the dSaC estimator in Corollary 8. However, both \( \hat{\theta}^{(1)} \) and \( \hat{\theta}_{LH}^{(1)} \) are not readily extended to the heterogeneous setting, as the one-step update procedure relies crucially on the \( N^{1/2} \)—consistency of the initial estimators of all the unknown parameters (van der Vaart, 1999), but the convergence rate of the block-specific estimators \( \lambda_k \) are only of order \( O_p(n^{1/2}) \).

A.10 Bias correction for statistical optimization under logistic regression model

Given observations \( \{(y_i, X_i)\}_{i=1}^n \), we now construct \( \hat{B}(\beta) \). Denote \( y = (y_1, y_2, \cdots, y_n)^T, X = (X_1, X_2, \cdots, X_n)^T \) and \( \hat{y} = (\hat{y}_1, \hat{y}_2, \cdots, \hat{y}_n) \) with \( \hat{y}_i = \logit(x_i^T \beta) \). Since
\[
d_{\text{logit}}(a) = \logit(a) \prod_{s=1}^j (1 - \logit(a)s),
\]
then we have \( \nabla M_n(\beta) = \frac{1}{n}X^T(\hat{y} - y) \), \( \nabla^2 M_n(\beta) = \frac{1}{n}X^T\text{diag}(\hat{y} \cdot (1 - \hat{y}))X \) and \( \nabla^3 M_n(\beta) = \frac{1}{n} \sum_{i=1}^n \hat{y}_i(1 - \hat{y}_i)(1 - 2\hat{y}_i)x_i \text{vec}(x_i \otimes x_i)^T \), where \( \cdot \) denotes the element-wise product of two vectors and \( \text{vec} \) is the vectorization operator. Then, the bias-correction formula is a combination of the gradients up to the third order.
Appendix B. Proofs

Without loss of generality, we assume equal sample size \( n \) in each data block. Besides, unless otherwise stated, we will use \( C, c, C_1 \) to denote positive constants independent of \( (n_k, K, N) \), and the same \( C_i \) can have different values from one context to another.

B.1 Lemmas

Before presenting the proofs of the theoretical results established in the main paper, we first establish some technical lemmas in the following sub-section.

**Lemma B.1** Suppose \( H \) and \( K \) are positive definite matrices of order \( p \), and \( X \) and \( Y \) are arbitrary \( p \times m \) matrices. Then, \( Q = X^T H^{-1} X + Y^T K^{-1} Y - (X + Y)^T (H + K)^{-1} (X + Y) \geq 0 \).

**Proof** Let \( A \) and \( B \) be defined as follows
\[
A = \begin{pmatrix} H & X \\ X^T & X^T H^{-1} X \end{pmatrix}, \quad B = \begin{pmatrix} K & Y \\ Y^T & Y^T K^{-1} Y \end{pmatrix}
\]

Since \( H, K \) are positive definite, we can directly check that \( A, B \) are positive semi-definite. Thus \( A + B \) is also positive semi-definite, and the conclusion follows. See Haynsworth (1970); Ando (1979) for more similar types of matrix inequalities.

**Lemma B.2** Under Assumptions 1 - 4 and Assumptions 5 - 6 with \( \min \{v, v_1 \} \geq 1 \), if \( K = o(n^{v_2}) \), then
\[
\sup_{1 \leq k \leq K} \| \hat{\theta}_k - \theta_k^* \|_2^2 \overset{p}{\to} 0.
\]

Besides, the following holds for all \( k = 1, 2, \ldots, K \) and \( 1 \leq v_2 \leq v_1 \)
\[
E \left( \| \hat{\theta}_k - \theta_k \|_2^{2v_2} \right) \leq C \left( \frac{R^{2v_2}}{n^{v_2}} + \left( \frac{1 + L^{2v}}{n^{v_2}} + \frac{R^{2v_1}}{n^{v_1}} \right) \right). \tag{33}
\]

**Proof** Let \( G_{n,k} = \frac{1}{n} \sum_{i=1}^{n} G_k(X_{k,i}), M_{n,k}(\theta) = \frac{1}{n} \sum_{i=1}^{n} M(X_{k,i}; \theta) \) and \( \delta_{\rho} = \min \{\rho, \rho \rho_-/4G\} \). For \( k = 1, \ldots, K \), define the following ”good events”:
\[
\mathcal{E}_k = \{G_{n,k} \leq 2G, \| \nabla^2_{\theta_k} M_{n,k}(\theta_k^*) - \nabla^2_{\theta_k} M_k(\theta_k^*) \|_2 \leq \frac{\rho \rho_-}{2}, \| \nabla_{\theta_k} M_{n,k}(\theta_k^*) \|_2 \leq \frac{(1 - \rho)\rho \rho_-}{2} \}, \tag{34}
\]

then by Lemma 6 in Zhang et al. (2013), we obtain that under the event \( \cap_{k=1}^{K} \mathcal{E}_k \)
\[
\| \hat{\theta}_k - \theta_k^* \|_2 \leq \frac{2\| \nabla_{\theta_k} M_{n,k}(\theta_k^*) \|_2}{(1 - \rho)\rho_-} \tag{35}
\]

holds for all \( k = 1, 2, \ldots, K \). Similar to the proof of Lemma C.1 in Jordan et al. (2019), we can show that there exist constants \( C_1, C_2, C_3 \) independent of \( (n, K, d, L, R) \) such that
\[
P(\cup_{k=1}^{K} \mathcal{E}_k^c) \leq K \left( \frac{C_1 + C_2 (log 2d) L^{2v}}{n^v} + \frac{C_3 R^{2v_1}}{n^{v_1}} \right). \]
Now For any $\epsilon > 0$ and $k \leq K$, we further define the events $\mathcal{E}_k' = \{\|\nabla_{\theta_k} M_{n,k}(\theta^*_k)\|_2 \leq (1 - \rho)\rho - \epsilon/2\}$. Then by Markov’s inequality and the union bound, there exist a positive constant $C_4$ depending on $\epsilon$ such that

$$P(\cup_{k=1}^K \mathcal{E}_k') \leq \frac{C_4(\log 2d)^{2v} L^{2v}}{n^v}.$$  

Thus, $\sup_{1 \leq k \leq K} \|\hat{\theta}_k - \theta^*_k\|_2 \xrightarrow{P} 0$ as $n \to \infty$ as long as $K = o(n^{\min\{v,v_1\}})$. Besides, the higher-order estimation error bound follows from the following decomposition

\[
E \left( \|\hat{\theta}_k - \theta^*_k\|_2^{2v} \right) = E \left( \|\hat{\theta}_k - \theta^*_k\|_2^{2v} \right) + E \left( \|\nabla_{\theta_k} M_{n,k}(\theta^*_k)\|_2^{2v} \right) + P \left( \mathcal{E}_k' \right) \\
\leq C \left( \frac{R^{2v_2}}{n^{v_2}} + \left( 1 + \frac{L^{2v}}{n^v} + \frac{R^{2v_1}}{n^{v_1}} \right) \right).
\]

\[\square\]

Lemma B.3 Inv($A$) : GL($\mathbb{R}^p$) → GL($\mathbb{R}^p$) : $A \mapsto A^{-1}$ is Lipschitz continuous at any $A \in$ GL($\mathbb{R}^p$), where GL($\mathbb{R}^p$) consists of all $p \times p$ invertible matrices of real numbers.

Proof Let $A_0 \in$ GL($\mathbb{R}^p$) be given. Denote $1/\|A_0^{-1}\|_2 = \delta > 0$. It follows that for all $x \in \mathbb{R}^p$ we have $\|x\|_2 = \|A_0^{-1}A_0x\|_2 \leq (1/\delta)\|A_0x\|_2$, namely $\|A_0x\|_2 \geq \delta\|x\|_2$. Assume that $\|A - A_0\|_2 < \delta/2$, then $\|Ax\|_2 \geq \|A_0x\|_2 - \|(A - A_0)x\|_2 \geq \frac{\delta}{2}\|x\|_2$, which means $A^{-1}$ exists and $\|A^{-1}\|_2 \leq 2/\delta$. Since $A^{-1} - A_0^{-1} = A^{-1}(A_0 - A)A_0^{-1}$, $\|A^{-1} - A_0^{-1}\|_2 \leq \|A^{-1}\|_2\|A_0 - A\|_2\|A_0^{-1}\|_2 \leq (2/\delta^2)\|A - A_0\|_2$, which completes the proof.

\[\square\]

Lemma B.4 Under Assumptions 1 - 4 and 7 and Assumptions 5 - 6 for $v, v_1 \geq 1$, if $K = o(n)$,

\[
\{n_k \sum_{k=1}^K H_k(\theta^*_k)^{-1} (\hat{\theta}_k - \phi^*)\}^T \{n_k \sum_{k=1}^K H_k(\theta^*_k)^{-1}\}^{-1}\{n_k \sum_{k=1}^K H_k(\theta^*_k)^{-1} (\hat{\theta}_k - \phi^*)\} \xrightarrow{d} \chi^2_{p_1}.
\]

Proof We prove for the case when $K \to \infty$, and it is straightforward to derive the proof for the fixed $K$ case. Since we have assumed equal sample size $n$ for simplicity, we can denote

\[
T_1 = \sqrt{N} \left\{ \frac{1}{K} \sum_{k=1}^K H_k(\theta^*_k)^{-1} - \frac{1}{2} \frac{1}{K} \sum_{k=1}^K H_k(\theta^*_k)^{-1} (\hat{\theta}_k - \phi^*) \right\},
\]

and the problem is equivalent to show that $\|T_1\|_2^2 \xrightarrow{\text{d}} \chi^2_{p_1}$ in distribution when $K = o(n)$. Since all the smoothness conditions in Assumptions 5 - 6 only holds locally, namely in the $U_\rho$ ball, so all the Taylor expansions hold only under the event $\cap_{k=1}^K \mathcal{E}_k$, where the definition of the event $\mathcal{E}_k$ can be found in the proof of Lemma B.2. Now, under the event $\cap_{k=1}^K \mathcal{E}_k$, by the integral form of Taylor’s expansion of $\nabla_{\theta_k} M_{n,k}(\theta_k)$ around the true parameter $\theta^*_k$, we have

\[
\hat{\theta}_k - \theta^*_k = -J_k(\theta^*_k)^{-1}\nabla_{\theta_k} M_{n,k}(\theta_k^*) + R_n^{(k)},
\]

(36)
where $R_{n}^{(k)} = R_{n,1}^{(k)} + R_{n,2}^{(k)}$.

$$R_{n,1}^{(k)} = -J_{k}(	heta_{k}^{*})^{-1} \{ \int_{0}^{1} \nabla_{\theta_{k}}^{2} M_{n,k}(\theta_{k}^{*} + t(\hat{\theta}_{k} - \theta_{k}^{*})) dt - \nabla_{\theta_{k}}^{2} M_{n,k}(\theta_{k}^{*}) \} (\hat{\theta}_{k} - \theta_{k}^{*})$$

and

$$R_{n,2}^{(k)} = -J_{k}(	heta_{k}^{*})^{-1} \{ \nabla_{\theta_{k}}^{2} M_{n,k}(\theta_{k}^{*}) - J_{k}(\theta_{k}^{*}) \} (\hat{\theta}_{k} - \theta_{k}^{*})$$

for each $k$. Recall the definition of $J_{\phi,\lambda}$ and $S_{\phi}$, if we denote

$$P_{k} = H_{k}(\theta_{k}^{*})^{-1} J_{\phi,\lambda}(\theta_{k}^{*})^{-1} (I_{p_{1}} \times p_{1}),$$

(37)

$$T_{1,0} = -\left\{ \frac{1}{K} \sum_{s=1}^{K} H_{s}(\theta_{s}^{*})^{-1} \right\}^{-\frac{1}{2}} \frac{1}{\sqrt{N}} \sum_{k=1}^{K} \sum_{i=1}^{n} P_{k} \psi_{\theta_{k}}(X_{k,i}; \theta_{k}^{*})$$

$$R_{1} = -\frac{1}{K} \sum_{k=1}^{K} H_{k}(\theta_{k}^{*})^{-1} \left\{ \frac{1}{K} \sum_{k=1}^{K} P_{k} \{ \int_{0}^{1} \nabla_{\theta_{k}}^{2} M_{n,k}(\theta_{k}^{*} + t(\hat{\theta}_{k} - \theta_{k}^{*})) dt - \nabla_{\theta_{k}}^{2} M_{n,k}(\theta_{k}^{*}) \} (\hat{\theta}_{k} - \theta_{k}^{*}) \right\}$$

and

$$R_{2} = -\frac{1}{K} \sum_{k=1}^{K} H_{k}(\theta_{k}^{*})^{-1} \left\{ \frac{1}{K} \sum_{k=1}^{K} P_{k} \{ \nabla_{\theta_{k}}^{2} M_{n,k}(\theta_{k}^{*}) - J_{k}(\theta_{k}^{*}) \} (\hat{\theta}_{k} - \theta_{k}^{*}) \right\}$$

then

$$T_{1} = (T_{1,0} + R_{1} + R_{2}) I(\cap_{k=1}^{K} E_{k}) + T_{1} \left( 1 - I(\cap_{k=1}^{K} E_{k}) \right)$$

$$= T_{1,0} + (R_{1} + R_{2}) I(\cap_{k=1}^{K} E_{k}) + (T_{1} + T_{1,0}) \left( 1 - I(\cap_{k=1}^{K} E_{k}) \right).$$

The proof of Lemma B.2 also shows that $P(\cap_{k=1}^{K} E_{k}) = 1 - O(K/n^{1/2})$, where $v_{2} = \min\{v_{1}, v_{2}\}$. Thus, it suffices to establish the asymptotic normality for $T_{1,0}$, show that the $R_{1}$ and $R_{2}$ terms are both $o_{p}(1)$ terms and then apply the Slutsky's lemma.

Considering the $T_{1,0}$ term, we apply the Cramer-Wold device to reduce the problem into a scalar case. For any non-zero $l \in \mathbb{R}^{p_{1}}$, let $l_{k}^{T} = -l^{T} \left( \frac{1}{K} \sum_{s=1}^{K} H_{k}(\theta_{k}^{*})^{-1} \right)^{-1/2} P_{k}$, then $l_{k}^{T} T_{1,0} = N^{-1/2} \sum_{k=1}^{K} \sum_{i=1}^{n} l_{k}^{T} \psi_{\theta_{k}}(X_{k,i}; \theta_{k}^{*})$. If we denote $Z_{K,k} = N^{-1/2} \sum_{i=1}^{n} l_{k}^{T} \psi_{\theta_{k}}(X_{k,i}; \theta_{k}^{*})$, then $l_{k}^{T} T_{1,0} = \sum_{k=1}^{K} Z_{K,k}$ and $E(Z_{K,k}) = 0$. Below we check the Lindeberg conditions. First, $\sum_{k=1}^{K} E(Z_{K,k}^{2}) = l_{k}^{T} l = \sigma_{l}^{2} > 0$. Second, for any $\epsilon > 0$,

$$\sum_{k=1}^{K} E(|Z_{K,k}|^{2}; |Z_{K,k}| > \epsilon) = \sum_{k=1}^{K} E(|Z_{K,k}|^{2} I_{|Z_{K,k}| > \epsilon})$$

$$= \sum_{k=1}^{K} (\int_{0}^{\epsilon} + \int_{\epsilon}^{\infty}) P(|Z_{K,k} I_{|Z_{K,k}| > \epsilon}| > t) dt$$

$$= \sum_{k=1}^{K} P(|Z_{K,k}| > \epsilon) + \sum_{k=1}^{K} \int_{\epsilon}^{\infty} P(|Z_{K,k}| > t) dt,$$

where the second equality comes from the tail-sum formula for expectations of absolute moments. Using Chebyshev’s inequality, Marcinkiewicz-Zygmund inequality with $b_{3}$ being the corresponding constant and Jensen’s inequality , we can show that

$$\sum_{k=1}^{K} P(|Z_{K,k}| > \epsilon) \leq \frac{b_{3}}{e^{3} K^{3/2}} \sum_{k=1}^{K} ||l_{k}||_{2}^{3} E(\left\| \psi_{\theta_{k}}(X_{k,1}; \theta_{k}^{*}) \right\|_{2}^{3}).$$

(38)
Recalling the definition of \( l_k \), we can use the boundedness of \( H_k(\theta_k^*) \) and \( \nabla_{\theta_k}^2 M_k(\theta_k^*) \) to show that \( \|l_k\|_2 \leq C\|l\|_2 \). Thus we have that

\[
\sum_{k=1}^{K} P(|Z_{K,k}| > \epsilon) \leq \frac{b_3 C}{e^{3}K^{3/2}} \|l\|_2 K \max_{1 \leq k \leq K} E\left(\|\psi_{\theta_k}(X_{k,1}; \theta_k^*)\|_2^2\right) \lesssim \frac{\max_{1 \leq k \leq K} E\left(\|\psi_{\theta_k}(X_{k,1}; \theta_k^*)\|_2^3\right)}{\sqrt{K}} \to 0.
\]

Now consider the \( \sum_{k=1}^{K} \int_{\epsilon}^{\infty} P(|Z_{K,k}| > t)dt \) term. By replacing the \( \epsilon \) in (38) with \( t \), we have

\[
\sum_{k=1}^{K} \int_{\epsilon}^{\infty} P(|Z_{K,k}| > t)dt \lesssim \frac{1}{\sqrt{K}} \int_{\epsilon}^{\infty} \frac{1}{t^3} dt \to 0.
\]

Thus we conclude that \( T_{1,0} \overset{d}{\to} \mathcal{N}(0, I_{p_1 \times p_2}) \). Now we consider the remainder term \( R_2 \). Since \( \|\frac{1}{K} \sum_{k=1}^{K} H_k(\theta_k^*)^{-1}\|_2 \) is bounded, we only need to show \( R_{2,1} \overset{d}{=} \{ \frac{1}{K} \sum_{k=1}^{K} H_k(\theta_k^*)^{-1}\} R_2 \) is \( o_p(1) \). Since \( |R_{2,1}| \leq \sqrt{\frac{K}{n} \sum_{k=1}^{K} \|P_k\|_2 \|\sqrt{n} (\nabla_{\theta_k}^2 M_k(\theta_k^*) - J_k(\theta_k^*))\|_2 \|\sqrt{n}(\theta_k - \theta_k^*)\|_2 \}
\]

by Markov’s inequality and H"older’s inequality, we will have

\[
P(\|R_{2,1}\| \geq \epsilon) \leq C_1 \sqrt{\frac{K}{n}} \sum_{k=1}^{K} \sqrt{E\left(\|\sqrt{n} (\nabla_{\theta_k}^2 M_k(\theta_k^*) - J_k(\theta_k^*))\|_2^2\right) E\left(\|\sqrt{n}(\theta_k - \theta_k^*)\|_2^2\right)}.
\]

From Lemma 7 of Zhang et al. (2013) and Assumption 5 with \( v \geq 1 \), we know that

\[
E\left(\|\sqrt{n} (\nabla_{\theta_k}^2 M_k(\theta_k^*) - J_k(\theta_k^*))\|_2\right) \leq C.
\]

On the other hand, by Lemma 6 of Zhang et al. (2013) and using the event \( \mathcal{E}_k \) we can show that

\[
E\left(\|\sqrt{n}(\theta_k - \theta_k^*)\|_2\right) \leq C_1. \text{ Since } K = o(n), \text{ we conclude that } R_2 = o_p(1).
\]

Considering the \( R_1 \) term, we can similarly prove that \( \|R_1\|_2 = o_p(1) \) by using the Lipschitz condition \( \|\nabla_{\theta_k}^2 M(x; \theta_k) - \nabla_{\theta_k}^2 M(x; \theta_k^*)\|_2 \leq G(x)\|\theta_k - \theta_k^*\|_2 \) as assumed in Assumption 5. The result follows via a direct application of the Slutsky’s lemma.

**Lemma B.5** Under the same conditions required by Lemma B.4, the following term is asymptotically negligible (i.e. \( o_p(1) \)):

\[
\sqrt{N} \left( \sum_{k=1}^{K} \sum_{s=1}^{K} n_s \hat{H}_s(\hat{\theta}_s)^{-1} - n_k \hat{H}_k(\hat{\theta}_k)^{-1} (\hat{\phi}_k - \phi^*) - \sum_{k=1}^{K} \sum_{s=1}^{K} n_s H_s(\theta_s^*)^{-1} - n_k H_k(\theta_k^*)^{-1} (\hat{\phi}_k - \phi^*) \right).
\]

**Proof** Denote the above term as \( T_2 \), then we have that

\[
\|T_2\|_2 \leq \sqrt{\frac{K}{n}} \left( \frac{1}{K} \sum_{k=1}^{K} \|\hat{H}_s(\hat{\theta}_s)^{-1} - H_s(\theta_s^*)^{-1}\|_2 \right) \sqrt{\frac{1}{K} \sum_{k=1}^{K} \|\sqrt{n}(\hat{\theta}_k - \theta_k^*)\|_2} \right)
\]

\[
+ \frac{1}{K} \sum_{k=1}^{K} \|H_k(\theta_k^*)^{-1}\|_2 \sqrt{(\frac{1}{K} \sum_{k=1}^{K} \|\hat{H}_s(\hat{\theta}_s)^{-1} - H_s(\theta_s^*)^{-1}\|_2 + \sqrt{n}(\hat{\phi}_k - \phi^*)\|_2)}
\]

\[
:= \sqrt{\frac{K}{n}} (T_2^{(1)} + T_2^{(2)}).
\]
Since $K = o(n)$, it suffices to show $T_2^{(1)}$ and $T_2^{(2)}$ are both $O_p(1)$. Under the event $A_K$ defined in Equation (61), we have $T_2^{(2)} I(A_K) \leq \frac{C}{\kappa} \sum_{k=1}^{K} \left( \sqrt{n} \| \hat{\Sigma}_{S,k}(\theta_k^*) - \Sigma_{S,k}(\theta_k^*) \|_2 + \sqrt{n} \| \hat{L}_k(\theta_k^*) - L_k(\theta_k^*) \|_2 + \| \sqrt{n}(\hat{\theta}_k - \theta_k^*) \|_2 \right) \| \sqrt{n}(\hat{\theta}_k - \theta_k^*) \|_2$. Thus for $v \geq 1$, $v_1 \geq 2$, by Markov’s inequality and Cauchy’s inequality we have

$$P(T_2^{(2)} > 1, A_K) \leq n \max_{1 \leq k \leq K} \left( C_1 \sqrt{E \left( \| \hat{\Sigma}_{S,k}(\theta_k^*) - \Sigma_{S,k}(\theta_k^*) \|_2^2 \right) E \left( \| \hat{\theta}_k - \theta_k^* \|_2^2 \right)} + C_2 \sqrt{E \left( \| \hat{L}_k(\theta_k^*) - L_k(\theta_k^*) \|_2^2 \right) E \left( \| \hat{\theta}_k - \theta_k^* \|_2^2 \right) + C_4 E \left( \| \hat{\theta}_k - \theta_k^* \|_2^2 \right)} \right) = O(1).$$

Since we have shown $P(A_K) \to 1$ if $K = o(n^6)$ with $\bar{v} = \min\{v, \frac{v_1}{2}\}$, and we have assumed that $K = o(n)$, we can conclude that $T_2^{(2)} = O_p(1)$. We can similarly show that $T_2^{(1)} = O_p(1)$. Now we complete the proof.

Lemma B.6 Let $A_1, A_2, \cdots, A_n \in \mathbb{S}^{p \times p}$, if

$$\left\| \begin{array}{c}
    \text{vec}(A_1)^T \\
    \text{vec}(A_2)^T \\
    \vdots \\
    \text{vec}(A_n)^T
\end{array} \right\|_2 \leq A \| \Delta \|_2^2 \quad \text{holds for } \forall \Delta \in \mathbb{R}^p,$n

denote $\hat{A} = (\text{vec}(A_1), \text{vec}(A_2), \cdots, \text{vec}(A_n))^T$.

Proof Since $\hat{A}(\Delta \otimes \Delta) = (\Delta^T A_1 \Delta, \Delta^T A_2 \Delta, \cdots, \Delta^T A_n \Delta)^T$, $A^2 \| \Delta \|_2^2 \geq \sum_{i=1}^{n} (\Delta^T A_i \Delta)^2$ which implies $\max_{i \leq n} \| A_i \|_2 \leq A$. On the other hand, for $B = (A_1, A_2, \cdots, A_n) \in \mathbb{R}^{p \times np}$, we have $\| B \|_2^2 = \lambda_{\max} \left( \sum_{i=1}^{n} A_i A_i^T \right) \leq \sum_{i=1}^{n} \lambda_{\max} (A_i A_i^T) = \sum_{i=1}^{n} \| A_i \|_2^2 \leq n A^2$, which gives $\| \hat{A} \|_2 = \| \hat{A}^T \|_2 \leq \sqrt{\sum_{i=1}^{n} \| \text{vec}(A_i) \|_2^2} = \sqrt{\sum_{i=1}^{n} \| A_i \|_F^2} \leq \sqrt{m}A$.

Lemma B.7 Under Assumptions 1 - 4 and 7 - 8, and Assumption 5 with $v, v_1 \geq 4$,

$$E \left( \| \hat{B}_k(\hat{\theta}_k) I_{\mathcal{E}_{k,bc}} - B_k(\theta_k^*) \|_2^2 \right) \leq \frac{C}{n}.$$

Proof Denote $\Delta_k = \hat{\theta}_k - \theta_k^*$. By the definition of the event $\mathcal{E}_{k,bc}$ given in Algorithm 2, we immediately have that $\| \hat{B}_k(\hat{\theta}_k) I_{\mathcal{E}_{k,bc}} - B_k(\theta_k^*) \|_2^2 \leq C n^2$. Below we first control the $\| Q_k(\theta_k^*) - \hat{Q}_k(\hat{\theta}_k) \|_2$ term. Note that $Q_k(\theta_k)$ and $Q_k(\theta_k)$ are exactly $-L_k^{-1}(\theta_k)$ and $\hat{L}_k(\theta_k)^{-1}$ defined in the proof of Theorem 3, thus under the event $\{ \| \hat{L}_k(\hat{\theta}_k) - L_k(\theta_k^*) \|_2 \leq \frac{\rho}{2} \}$, we have $\| Q_k(\theta_k^*) - \hat{Q}_k(\hat{\theta}_k) \|_2 \leq \frac{\rho}{2^2} \| \hat{L}_k(\hat{\theta}_k) - L_k(\theta_k^*) \|_2$. Besides, when $\| \Delta_k \|_2 \leq \rho$, we have

$$\| \hat{L}_k(\hat{\theta}_k) - L_k(\theta_k^*) \|_2 \leq \frac{1}{n} \sum_{i=1}^{n} G(X_{k,i}) \| \Delta_k \|_2 + \| \hat{L}_k(\theta_k^*) - L_k(\theta_k^*) \|_2.$$  

(39)
Without loss of generality, we can assume $\rho_- \leq 8G\rho$, then if we define $E_{Q,k} = \{\|\Delta_k\|_2 \leq \frac{1}{8G}, G_{n,k} \leq 2G, \|L_k(\theta_k^*^m) - L_k(\theta_k^*)\|_2 < \frac{\rho_+}{2}\}$, then

$$
\|\hat{Q}_k(\hat{\theta}_k)\|_2 \leq \left(\|Q_k(\theta_k^*) - \hat{Q}_k(\hat{\theta}_k)\|_2 + \|Q_k(\theta_k^*)\|_2\right)1_{E_{Q,k}} \leq \frac{1}{\rho_-} + \rho_-\\
\|Q_k(\theta_k^*) - \hat{Q}_k(\hat{\theta}_k)\|_2 \leq \left(G\|\nabla_{\theta_k} M_{n,k}(\theta_k^*)\|_2 + \|\hat{L}_k(\theta_k^*) - L_k(\theta_k^*)\|_2\right).
$$

Using union bound and Markov’s inequality, it is easy to show

$$
P(\{E_{Q,k}\}^c) \leq C \left(\frac{1 + L^2}{n^v} + \frac{R^{2v_1}}{n^{v_1}}\right).
$$

Besides, under this event, we can decompose the estimation error using the event $E_k$ and obtain

$$
E\left(1_{E_{Q,k}} \|Q_k(\theta_k^*) - \hat{Q}_k(\hat{\theta}_k)\|_2^2\right) \leq C\left(E \left(\|\nabla_{\theta_k} M_{n,k}(\theta_k^*)\|_2^2\right) + E \left(\|\hat{L}_k(\theta_k^*) - L_k(\theta_k^*)\|_2^2\right) + P(\{E_k\}^c)\right)
\leq C\left(\frac{R^2 + L^2}{n} + P(\{E_k\}^c)\right).
$$

(40)

It is noted that

$$
\|B_k(\hat{\theta}_k) - B_k(\theta_k^*)\|_2^2 \\
\leq 2\|\hat{Q}_k(\hat{\theta}_k) - Q_k(\theta_k^*)\|_2 \sum\frac{1}{n} \sum_{i=1}^n \hat{v}_{i,k}(\hat{\theta}_k) \hat{d}_{i,k}(\hat{\theta}_k) - Q_k(\theta_k^*)E \left(v_{1,k}(\theta_k^*)d_{1,k}(\theta_k^*)\right)\|_2
\] + \frac{1}{2} \|\hat{Q}_k(\hat{\theta}_k) \hat{H}_{3,k}(\hat{\theta}_k) \|_2 \sum\frac{1}{n} \sum_{i=1}^n \hat{d}_{i,k}(\hat{\theta}_k) \otimes \hat{d}_{i,k}(\hat{\theta}_k) - Q_k(\theta_k^*)H_{3,k}(\theta_k^*)E \left(d_{1,k}(\theta_k^*) \otimes d_{1,k}(\theta_k^*)\right)\|_2
\]
$$
\leq 2\Omega_{k,1} + \frac{1}{2}\Omega_{k,2},
$$

then we can bound those two terms respectively. For $\Omega_{k,1}$, under the event $E_{Q,k}$ we have

$$
\Omega_{k,1}1_{E_{Q,k}}
\leq 2\left(\|\hat{Q}_k(\hat{\theta}_k)\|_2 \sum\frac{1}{n} \sum_{i=1}^n \hat{v}_{i,k}(\hat{\theta}_k) \hat{d}_{i,k}(\hat{\theta}_k) - E \left(v_{1,k}(\theta_k^*)d_{1,k}(\theta_k^*)\right)\|_2 + 1_{E_{Q,k}} \|Q_k(\theta_k^*) - \hat{Q}_k(\hat{\theta}_k)\|_2^2 \|E \left(v_{1,k}(\theta_k^*)d_{1,k}(\theta_k^*)\right)\|_2^2\right)
\leq C\left(\frac{1}{n} \sum\frac{1}{n} \sum_{i=1}^n \hat{v}_{i,k}(\hat{\theta}_k) \hat{d}_{i,k}(\hat{\theta}_k) - \hat{v}_{i,k}(\theta_k^*) \hat{d}_{i,k}(\theta_k^*)\|_2\right) + 1_{E_{Q,k}} \|Q_k(\theta_k^*) - \hat{Q}_k(\hat{\theta}_k)\|_2^2
\]
$$
\leq C\left(\frac{1}{n} \sum\frac{1}{n} \sum_{i=1}^n \hat{v}_{i,k}(\hat{\theta}_k) \hat{d}_{i,k}(\hat{\theta}_k) - \hat{v}_{i,k}(\theta_k^*) \hat{d}_{i,k}(\theta_k^*)\|_2\right) + 1_{E_{Q,k}} \|Q_k(\theta_k^*) - \hat{Q}_k(\hat{\theta}_k)\|_2^2
$$
\leq C\left(\frac{1}{n} \sum\frac{1}{n} \sum_{i=1}^n \hat{v}_{i,k}(\hat{\theta}_k) \hat{d}_{i,k}(\hat{\theta}_k) - \hat{v}_{i,k}(\theta_k^*) \hat{d}_{i,k}(\theta_k^*)\|_2\right) + 1_{E_{Q,k}} \|Q_k(\theta_k^*) - \hat{Q}_k(\hat{\theta}_k)\|_2^2.
$$

(41)

By Lemma 7 in Zhang et al. (2013), we have

$$
E\left(\frac{1}{n} \sum\frac{1}{n} \sum_{i=1}^n \hat{v}_{i,k}(\theta_k^*) \hat{d}_{i,k}(\theta_k^*) - E \left(v_{1,k}(\theta_k^*)d_{1,k}(\theta_k^*)\right)\|_2\right) \leq C\frac{R^2L^2}{n}.
$$

36
Besides, given (40), it suffices to control $E\left(\Omega_{k,1}^{(1)}\right)$. Note that

$$\Omega_{k,1}^{(1)} \leq 2\left\| \frac{1}{n} \sum_{i=1}^{n} (\hat{v}_{i,k}(\hat{\theta}_k) - \hat{v}_{i,k}(\theta_k^{*})) \hat{d}_{i,k}(\theta_k) \right\|_2^2 1_{E_{Q,k}} + 2\left\| \frac{1}{n} \sum_{i=1}^{n} \hat{v}_{i,k}(\theta_k^{*}) (\hat{d}_{i,k}(\theta_k) - d_{i,k}(\theta_k^{*})) \right\|_2^2 1_{E_{Q,k}}$$

$$:= 2(\Omega_{k,1}^{(2)} + \Omega_{k,1}^{(3)}).$$

Under the event $E_{Q,k} \cap E_k$, we have $\|\hat{v}_{i,k}(\hat{\theta}_k) - \hat{v}_{i,k}(\theta_k^{*})\|_2 \leq CG(X_{k,i}) \|\nabla_{\theta_k} M_{n,k}(\theta_k^{*})\|_2$. Besides, note that $\|\nabla_{\theta_k} M_{n,k}(\theta_k^{*})\|_2$ is bounded under $E_k$, then by Taylor’s expansion we can show that

$$\|\nabla_{\theta_k} M(X_{k,i}; \hat{\theta}_k) - \nabla_{\theta_k} M(X_{k,i}; \theta_k^{*})\|_2 \leq C (G(X_{k,i}) \|\nabla_{\theta_k} M_{n,k}(\theta_k^{*})\|_2 + \|\nabla_{\theta_k} M(X_{k,i}; \theta_k^{*})\|_2 \|\nabla_{\theta_k} M_{n,k}(\theta_k^{*})\|_2) 1_{E_k}$$

$$\leq C (G(X_{k,i}) + \|\nabla_{\theta_k} M(X_{k,i}; \theta_k^{*})\|_2 \|\nabla_{\theta_k} M_{n,k}(\theta_k^{*})\|_2) 1_{E_k}. \tag{42}$$

Now by Hölder’s inequality, we can show that

$$E\left(\Omega_{k,1}^{(2)} 1_{E_k}\right) \leq CE \left(\|\nabla_{\theta_k} M_{n,k}(\theta_k^{*})\|_2^2 \sum_{i=1}^{n} G^2(X_{k,i}) \|\nabla_{\theta_k} M(X_{k,i}; \hat{\theta}_k)\|_2^2 1_{E_k}\right)$$

$$\leq C \sum_{i=1}^{n} \left( E\left(\|\nabla_{\theta_k} M_{n,k}(\theta_k^{*})\|_2^6\right) E\left(G^6(X_{k,i})\right) E\left(\|\nabla_{\theta_k} M(X_{k,i}; \hat{\theta}_k)\|_2^6 1_{E_k}\right)\right)^{1/3}$$

$$\leq C G^2 R^2 (G^2 + L^2 + R^2).$$

For $E\left(\Omega_{k,1}^{(3)} 1_{E_k}\right)$, first note that

$$\|\hat{d}_{i,k}(\hat{\theta}_k) - d_{i,k}(\theta_k^{*})\|_2 \leq \|\hat{Q}_k(\hat{\theta}_k) - Q_k(\theta_k^{*})\|_2 \|\nabla_{\theta_k} M(X_{k,i}; \theta_k^{*})\|_2 + ||\hat{Q}_k(\hat{\theta}_k)\|_2 \|\nabla_{\theta_k} M(X_{k,i}; \hat{\theta}_k) - \nabla_{\theta_k} M(X_{k,i}; \theta_k^{*})\|_2,$$

then combined with (39) and (42), we have that

$$E\left(\Omega_{k,1}^{(3)} 1_{E_k}\right) \leq C \sum_{i=1}^{n} \left( E\left(\|\nabla_{\theta_k} M(X_{k,i}; \theta_k^{*})\|_2^2 \left(G^2 \|\nabla_{\theta_k} M_{n,k}(\theta_k^{*})\|_2 + \|\nabla_{\theta_k} M_{n,k}(\theta_k^{*}) - \nabla_{\theta_k} M_{n,k}(\theta_k^{*})\|_2 \right) \|\nabla_{\theta_k} M(X_{k,i}; \theta_k^{*})\|_2^2 \right)ight)$$

$$\leq C L^2 R^2 \left(L^2 + G^2 + G^2 R^2\right).$$

Now we consider $\Omega_{k,2}$. First, by Assumption 5 and Lemma B.6, we can show

$$\|\nabla_{\theta_k}^2 M(X_{k,i}; \theta_k^{*}) - H_{3,k}(\theta_k^{*})\|_2 \leq C(G(X_{k,i}) + G), \tag{44}$$
leading to \( E \left( \| \hat{H}_{3,k}(\theta_k^*) - H_{3,k}(\theta_k^*) \|_2^2 \right) \) \( \leq \frac{CC'^{2u}}{n} \). Besides, using Assumption 8 and Lemma B.6.

\[
\| \hat{H}_{3,k}(\theta_k^*) - H_{3,k}(\theta_k^*) \|_2 2\varepsilon_k \leq \frac{C}{n} \sum_{i=1}^{n} A(X_{k,i}) \| \nabla_{\theta_k} M_{n,k}(\theta_k^*) \|_2 1\varepsilon_k.
\]

\[\Omega_{k,2}\]

\[
\leq C_1 \| \hat{Q}_k(\theta_k) \hat{H}_{3,k}(\theta_k) - \frac{1}{n} \sum_{i=1}^{n} \hat{d}_{i,k}(\theta_k) \hat{d}_{i,k}(\theta_k) - Q_k(\theta_k^*) H_{3,k}(\theta_k^*) \|_2^2
\]

\[
+ C_2 G^2 \| \frac{1}{n} \sum_{i=1}^{n} \hat{d}_{i,k}(\theta_k^*) \hat{d}_{i,k}(\theta_k^*) - E \left( d_{1,k}(\theta_k^*) \hat{d}_{1,k}(\theta_k^*) \right) \|_2^2
\]

\[
\leq C_1 \| \hat{Q}_k(\theta_k) \hat{H}_{3,k}(\theta_k) - Q_k(\theta_k^*) H_{3,k}(\theta_k^*) \|_2^2
\]

\[
+ C_2 G^2 \| \frac{1}{n} \sum_{i=1}^{n} \hat{d}_{i,k}(\theta_k^*) \hat{d}_{i,k}(\theta_k^*) - \frac{1}{n} \sum_{i=1}^{n} d_{i,k}(\theta_k^*) \hat{d}_{i,k}(\theta_k^*) \|_2^2
\]

\[
+ C_3 G^2 \| \frac{1}{n} \sum_{i=1}^{n} d_{i,k}(\theta_k^*) \hat{d}_{i,k}(\theta_k^*) - E \left( d_{1,k}(\theta_k^*) \hat{d}_{1,k}(\theta_k^*) \right) \|_2^2
\]

\[
:= C \left( \Omega_{k,2}^{(1)} + G^2 \Omega_{k,2}^{(2)} + G^2 \Omega_{k,2}^{(3)} \right)
\]

Using lemma 7 in Zhang et al. (2013), we have \( E \left( \Omega_{k,2}^{(3)} \right) \leq C \frac{L^4 R^4}{n} \). Considering \( \Omega_{k,2}^{(1)} \),

\[
\Omega_{k,2}^{(1)} 1\varepsilon_{Q,k,\cap \varepsilon_k}
\]

\[
\leq C \left( \| \hat{H}_{3,k}(\theta_k) - H_{3,k}(\theta_k^*) \|_2^2 + G^2 \| \hat{Q}_k(\theta_k) - Q_k(\theta_k^*) \|_2^2 \right) \left( \frac{1}{n} \sum_{i=1}^{n} \| \nabla_{\theta_k} M(X_{k,i}; \hat{\theta}_k) \|_2^2 \right)^2 1\varepsilon_{Q,k,\cap \varepsilon_k},
\]

then by Hölder’s inequality, we can show that

\[
E \left( \Omega_{k,2}^{(1)} 1\varepsilon_{Q,k,\cap \varepsilon_k} \right) \leq C \left( \sqrt{E \left( \| \hat{H}_{3,k}(\theta_k) - H_{3,k}(\theta_k^*) \|_2^2 1\varepsilon_{Q,k,\cap \varepsilon_k} \right)} + G^2 \sqrt{E \left( \| \hat{Q}_k(\theta_k) - Q_k(\theta_k^*) \|_2^2 1\varepsilon_{Q,k,\cap \varepsilon_k} \right)} \right) + \frac{G^2}{n} \sum_{i=1}^{n} \| \nabla_{\theta_k} M(X_{k,i}; \hat{\theta}_k) \|_2^2
\]

\[
\leq C \left( G^2 (1 + L^2 + R^2) + A^2 R^2 \right) (G^4 + R^4 + L^4).
\]

Considering \( \Omega_{k,2}^{(2)} \), note for any two p-dimensional vectors \( \ell_1 \) and \( \ell_2 \), we have

\[
\| \ell_1 \otimes \ell_1 - \ell_2 \otimes \ell_2 \|_2^2 = \| \ell_1^T \ell_1 - \ell_2^T \ell_2 \|_2^2 \leq 2 \left( \| \ell_1 \|_2^2 \| \ell_2 \|_2^2 \right),
\]

then using (42) and (43), we can show that

\[
E \left( \Omega_{k,2}^{(2)} 1\varepsilon_{Q,k,\cap \varepsilon_k} \right) \leq C \frac{R^2 (G^2 + R^2 + L^2)^2}{n}.
\]
Finally, we consider $\mathcal{E}_{k,bc}$ and we can show that
\[
P(\mathcal{E}_{k,bc}^c) \leq P(\mathcal{E}_{k,bc}^c \cap \mathcal{E}_{Q,k} \cap \mathcal{E}_k) + P((\mathcal{E}_{Q,k} \cap \mathcal{E}_k)^c)
\leq \frac{C}{n^2} E \left( \| \hat{B}(\theta_k) - B_k(\theta_k^*) \|^2 \right) + CP((\mathcal{E}_{Q,k} \cap \mathcal{E}_k)^c).
\]

Collecting all the above results, we have the following upper-bound
\[
E \left( \| \hat{B}_k(\theta_k)_{1\mathcal{E}_{k,bc}} - B_k(\theta_k^*) \|^2 \right)
\leq E \left( \| \hat{B}(\theta_k) - B_k(\theta_k^*) \|^2 \right) + CP((\mathcal{E}_{Q,k} \cap \mathcal{E}_k)^c)
\leq \frac{C}{n^2} \left( R^2 + L^2 + R^2 L^2 + G^2 R^2 (G^2 + 2R^2 + L^2) + L^2 R^2 (L^2 + G^2 + G^2 R^2) + R^2 (G^2 + R^2 + L^2)^2 
+ (G^2 (1 + L^2 + R^2) + A^2 R^2) (G^4 + R^4 + L^4) \right) + CP((\mathcal{E}_{Q,k} \cap \mathcal{E}_k)^c). \tag{46}
\]

This concludes the proof. \hfill \blacksquare

Now let the pseudo debiased weighted distributed estimator be $\hat{\phi}_{pdWD} = \sum_{k=1}^K W_k(\theta_k^*) (\hat{\phi}_k - \frac{1}{n} B_k^1(\theta_k^*))$, we then give the following lemma on the MSE bound of this estimator.

**Lemma B.8** Under Assumptions 1 - 4 and 7 - 8, and Assumption 5 with $v, v_1 \geq 4$,
\[
E \left( \| \hat{\phi}_{pdWD} - \phi^* \|^2 \right) \leq \frac{C_1}{nK} + \frac{C_2}{n^2K} + \frac{C_3}{n^3}. \tag{47}
\]

**Proof** Under the event $\mathcal{E}_k$ defined in the Lemma B.2, we have that
\[
0 = \nabla_{\theta_k} M_{n,k}(\theta_k^* + t\Delta_k) + \frac{1}{2} \left( \int_0^1 \nabla_{\theta_k}^2 M_{n,k}(\theta_k^* + t\Delta_k) dt \right) (\Delta_k \otimes \Delta_k)
\]
\[
= \nabla_{\theta_k} M_{n,k}(\theta_k^*) + \frac{1}{2} \nabla_{\theta_k}^2 M_{n,k}(\theta_k^*) \Delta_k + \frac{1}{2} \nabla_{\theta_k}^3 M_{n,k}(\theta_k^*) (\Delta_k \otimes \Delta_k)
+ (\nabla_{\theta_k}^2 M_{n,k}(\theta_k^*) - \nabla_{\theta_k}^2 M_{n,k}(\theta_k^*)) \Delta_k + \frac{1}{2} \left( \int_0^1 \nabla_{\theta_k}^3 M_{n,k}(\theta_k^* + t\Delta_k) dt - \nabla_{\theta_k}^3 M_{n,k}(\theta_k^*) \right) (\Delta_k \otimes \Delta_k).
\]

Recall that we have denoted $J_k(\theta_k) = \nabla_{\theta_k}^2 M_{n,k}(\theta_k^*)$, solve for the above equation and we will have
\[
\Delta_k = -J_k(\theta_k^*)^{-1} \nabla_{\theta_k} M_{n,k}(\theta_k^*) - J_k(\theta_k^*)^{-1} (\nabla_{\theta_k}^2 M_{n,k}(\theta_k^*) - \nabla_{\theta_k}^2 M_{n,k}(\theta_k^*)) \Delta_k
\]
\[
- \frac{1}{2} J_k(\theta_k^*)^{-1} \nabla_{\theta_k}^3 M_{n,k}(\theta_k^*) (\Delta_k \otimes \Delta_k)
\]
\[
- \frac{1}{2} J_k(\theta_k^*)^{-1} \left( \int_0^1 \nabla_{\theta_k}^3 M_{n,k}(\theta_k^* + t\Delta_k) dt - \nabla_{\theta_k}^3 M_{n,k}(\theta_k^*) \right) (\Delta_k \otimes \Delta_k). \tag{48}
\]

Recalling the definition of $W_k(\theta_k^*)$, we have that $\| \phi_{pdWD} - \phi^* \|^2_2 \leq C \| \frac{1}{K} \sum_{k=1}^K H_k(\theta_k^*)^{-1} (\hat{\phi}_k - \phi^* - \frac{1}{n} B_k^1(\theta_k^*)) \|^2_2 = C \| \frac{1}{K} \sum_{k=1}^K H_k(\theta_k^*)(\Delta_k - \frac{1}{n} B_k(\theta_k^*)) \|^2_2$, where $H_k(\theta_k^*) = (H_k(\theta_k^*)^{-1} 0)$ and
thus $\|\bar{H}_k(\theta_k^*)\|_2 = \|H_k(\theta_k^*)\|_2$. Denote
\[
\Omega_{k,1} = (\nabla^2_{\theta_k} M_{n,k}(\theta_k^*) - \nabla^2_{\theta_k} M_k(\theta_k^*)) \Delta_k - \frac{1}{n} E (v_{1,k}(\theta_k^*) d_{1,k}(\theta_k^*)) ,
\]
\[
\Omega_{k,2} = (\Delta_k \otimes \Delta_k) - \frac{1}{n} E (d_{1,k}(\theta_k^*) \otimes d_{1,k}(\theta_k^*)) \quad \text{and}
\]
\[
\Omega_{k,3} = \left( \int_0^1 \nabla^2_{\theta_k} M_{n,k}(\theta_k^* + t \Delta_k) dt - \nabla^2_{\theta_k} M_k(\theta_k^*) \right) (\Delta_k \otimes \Delta_k), \quad \text{then} \quad (49)
\]
\[
\Delta_k - \frac{1}{n} B_k(\theta_k^*) = - \left( \frac{1}{n} \sum_{i=1}^n d_{i,k}(\theta_k^*) + Q_k(\theta_k^*) (\Omega_{k,1} + \frac{1}{2} H_{3,k}(\theta_k^*) \Omega_{k,2} + \frac{1}{2} \Omega_{k,3}) \right) I(\mathcal{E}_k)
\]
\[
+ \Delta_k I(\mathcal{E}_k^C). \quad (50)
\]
Considering $\Omega_{k,1}$, denote $\Omega_{k,1}^{(1)}$ and $\Omega_{k,1}^{(2)}$ as follows that $\Omega_{k,1} = \Omega_{k,1}^{(1)} + \Omega_{k,1}^{(2)}$.
\[
\Omega_{k,1}^{(1)} = (\nabla^2_{\theta_k} M_{n,k}(\theta_k^*) - \nabla^2_{\theta_k} M_k(\theta_k^*)) (\Delta_k - \frac{1}{n} \sum_{i=1}^n d_{i,k}(\theta_k^*)) \quad \text{and}
\]
\[
\Omega_{k,1}^{(2)} = (\nabla^2_{\theta_k} M_{n,k}(\theta_k^*) - \nabla^2_{\theta_k} M_k(\theta_k^*)) \frac{1}{n} \sum_{i=1}^n d_{i,k}(\theta_k^*) - \frac{1}{n} E (v_{1,k}(\theta_k^*) d_{1,k}(\theta_k^*)).
\]
For $\Omega_{k,1}^{(1)}$, we can show by Taylor’s expansion that
\[
\Delta_k - \frac{1}{n} \sum_{i=1}^n d_{i,k}(\theta_k^*) 1_{\mathcal{E}_k} = Q_k(\theta_k^*) \left( \int_0^1 \nabla^2_{\theta_k} M_{n,k}(\theta_k^* + t \Delta_k) dt - \nabla^2_{\theta_k} M_k(\theta_k^*) \right) \Delta_k 1_{\mathcal{E}_k},
\]
then using Hölder’s inequality we can show that
\[
E \left( \|\Omega_{k,1}^{(1)}\|_2^2 I_{\mathcal{E}_k} \right) \leq \frac{CG^4 R^2 (G^2 + 1)}{n^3}. \quad (51)
\]
For $\Omega_{k,1}^{(2)}$, by the independence among the observations, it is easy to first show that $E \left( \Omega_{k,1}^{(2)} \right) = 0$. Denote $e_{ij} = E (v_{i,k}(\theta_k^*) d_{j,k}(\theta_k^*))$, then we have
\[
E \left( \|\Omega_{k,1}^{(2)}\|_2^2 \right) = \frac{1}{n^4} \sum_{i,j=1}^n \sum_{s,t=1}^n E \left( (v_{i,k}(\theta_k^*) d_{j,k}(\theta_k^*) - e_{ij})^T (v_{s,k}(\theta_k^*) d_{t,k}(\theta_k^*) - e_{st}) \right). \quad (52)
\]
By a conditioning argument and independence among observations, it is straightforward to show that if the set $\{i, j, s, t\}$ has three or four unique elements, then $E (v_{i,k}(\theta_k^*) d_{j,k}(\theta_k^*) - e_{ij})^T (v_{s,k}(\theta_k^*) d_{t,k}(\theta_k^*) - e_{st}) = 0$. Thus the RHS of Equation (52) has at most $O(n^2)$ non-zero elements and each of these non-zero elements can be bounded using Hölder’s inequality. Since $E \left( \|v_{1,k}(\theta_k^*) d_{1,k}(\theta_k^*) - e_{11}\|_2^2 \right) \leq C(LR)^2$, we have $E \left( \|\Omega_{k,1}^{(2)}\|_2^2 \right) \leq C(LR)^2$. By independence among different $\Omega_{k,1}^{(2)}$, we can directly show that
\[
E \left( \left\| \frac{1}{K} \sum_{k=1}^K \bar{H}_k(\theta_k^*) Q_k(\theta_k^*) \Omega_{k,1} \right\|_2^2 \right) \leq C \left( \frac{L^2 R^2}{n^2 K} + \frac{G^2 R^2 (G^2 + 1)}{n^3} \right).
\]
For $\Omega_{k,2}$ appeared in (49), we define $\Omega_{k,2}^{(1)}$ and $\Omega_{k,2}^{(2)}$ as follows such that $\Omega_{k,2} = \Omega_{k,2}^{(1)} + \Omega_{k,2}^{(2)}$:

$$\Omega_{k,2}^{(1)} = (\Delta_k \otimes \Delta_k) - \left( \frac{1}{n} \sum_{i=1}^{n} d_{i,k}(\theta^*_k) \right) \otimes \left( \frac{1}{n} \sum_{i=1}^{n} d_{i,k}(\theta^*_k) \right) \quad \text{and}$$

$$\Omega_{k,2}^{(2)} = \left( \frac{1}{n} \sum_{i=1}^{n} d_{i,k}(\theta^*_k) \right) \otimes \left( \frac{1}{n} \sum_{i=1}^{n} d_{i,k}(\theta^*_k) \right) - \frac{1}{n} \mathbb{E} \left( d_{1,k}(\theta^*_k) \otimes d_{1,k}(\theta^*_k) \right).$$

Similar to (51), we can show that

$$E\| \frac{1}{K} \sum_{k=1}^{K} \tilde{H}_k(\theta^*_k) Q_k(\theta^*_k) H_{3,k}(\theta^*_k) \Omega_{k,2}^{(2)} \|_2^2 \leq \frac{CR^4}{n^2K}.$$ 

Besides, due to (45) and (51), we can show that $E \left( \| \Omega_{k,2}^{(1)} \|_2^2 1_{\mathcal{E}_k} \right) \leq C\frac{G^2R^4}{n^3}$. For $\Omega_{k,3}$ in (49), combined with (44) and the Lipschitz continuity of $\nabla^3_{\theta_k} M(X_{k,1}, \theta_k)$ with respect to $\theta_k$ in $U_k$, we can show that $E \left( \| \Omega_{k,3} \|_2^2 1_{\mathcal{E}_k} \right) \leq C\frac{(\Delta^2 R^2 + G^2 R^3)}{n^3}$. For $\Delta_k I(\mathcal{E}_k^C)$, $E \left( \| \Delta_k I(\mathcal{E}_k^C) \|_2^2 \right) \leq CP(\mathcal{E}_k^C)$. In summary, we have the following MSE bound of the pdWD estimator:

$$E \left( \| \hat{\phi}_{\text{pdWD}} - \phi^* \|_2^2 \right) \leq C_1 \frac{R^2}{nK} + C_2 \frac{R^2(L^2 + R^2)}{n^2K} + C_3 \frac{G^2R^2(G^2 + R^2 + G^4)}{n^3} + A^2R^6 + C_4 \sum_{k=1}^{K} P(\mathcal{E}_k^C).$$

The asymptotic normality of the pdWD estimator is established in the following lemma.

**Lemma B.9** Under Assumptions 1 - 4 and 7 - 8, and Assumption 5 with $v, v_1 \geq 4$, if $K = o(n^2)$,

$$(\hat{\phi}_{\text{pdWD}} - \phi^*)^T \left( \sum_{k=1}^{K} n_k H_k(\theta^*_k)^{-1} \right) (\hat{\phi}_{\text{pdWD}} - \phi^*) \overset{d}{\to} \chi_{v_1}^2.$$

**Proof** Since

$$\hat{\phi}_{\text{pdWD}} - \phi^* = \left( \frac{1}{K} \sum_{k=1}^{K} H_k(\theta^*_k)^{-1} \right)^{-1} \frac{1}{K} \sum_{k=1}^{K} \tilde{H}_k(\theta^*_k) \left( \Delta_k - \frac{1}{n} B_k(\theta^*_k) \right).$$

Using the expansion (50) and other results in the proof of Lemma B.8. when $K = o(n^2)$,

$$\frac{1}{K} \sum_{k=1}^{K} \tilde{H}_k(\theta^*_k)(\Delta_k - \frac{1}{n} B_k(\theta^*_k)) = \frac{1}{Kn} \sum_{k=1}^{K} \sum_{i=1}^{n} \tilde{H}_k(\theta^*_k) d_{i,k}(\theta^*_k) + o_P(1). \quad (53)$$

Then, the proof is completed with a direct application of the central limit theorem.
B.2 Proof of Proposition 1

**Proof** The consistency of the local estimator $\hat{\theta}_k$ is implied by Lemma 6 of Zhang et al. (2013). Below we show the consistency of the global estimator $\hat{\theta}_{\text{full}}$. Define the global objective function $\bar{M}(\bar{X}, \theta) = (1/K) \sum_{k=1}^{K} M(X_k, \theta_k)$ and the global expected objective function $\bar{M}(\theta) = E \left( \bar{M}(\bar{X}, \theta) \right)$, where $\bar{X} = (X_1^T, X_2^T, ..., X_K^T)^T$ and $X_k$ is sampled from the distribution $F_k$. Then, equivalently, we have

$$\theta^* = \arg\min_{\theta \in \Theta} E \left( \bar{M}(\bar{X}; \theta) \right) \quad \text{and} \quad \hat{\theta}_{\text{full}} = \arg\min_{\theta \in \Theta} \frac{1}{n} \sum_{i=1}^{n} \bar{M}(\bar{X}_i, \theta),$$

where $\bar{X}_i = (X_{1,i}^T, X_{2,i}^T, ..., X_{K,i}^T)^T$. Now we can show that

$$E \left( \|\nabla_{\theta} \bar{M}(\bar{X}_i, \theta^*)\|_2^2 \right) \leq R^{2\nu_1} \quad \text{and} \quad E \left( \|\nabla_{\theta} \bar{M}(\bar{X}_i, \theta^*) - \nabla_{\theta} \bar{M}(\theta^*)\|_2^2 \right) \leq L^{2\nu}$$

hold by a direct application of Lemma 7 of Zhang et al. (2013). Besides, for all $\theta, \theta' \in U$ with $U = \{\theta : \|\theta - \theta^*\|_2 \leq \rho\}$, we have

$$\|\nabla_{\theta} \bar{M}(\bar{X}, \theta) - \nabla_{\theta} \bar{M}(\bar{X}, \theta')\|_2 \leq \left( \frac{1}{K} \sum_{k=1}^{K} G(X_k) \right) \|\theta - \theta'\|_2 \quad \text{and} \quad E \left( \frac{1}{K} \sum_{k=1}^{K} G(X_k) \right)^{2\nu} \leq G^{2\nu}. $$

Besides, we can also show that

$$\nabla_{\theta}^2 \bar{M}(\theta^*) \succeq \begin{pmatrix} \rho I_{P_1 \times P_1} & 0 \\ 0 & \frac{\sigma}{K} I_{K P_2 \times K P_2} \end{pmatrix} \succeq \frac{\rho}{K} I_{(P_1 + K P_2) \times (P_1 + K P_2)}.$$

It remains to apply Lemma 6 of Zhang et al. (2013) to obtain the consistency of $\hat{\theta}_{\text{full}}$. 

B.3 Proof of Theorem 2

**Proof** See the proof of Lemma B.4.

B.4 Proof of Theorem 3

**Proof** Note that

$$\|\hat{\phi} - \phi^*\|_2 \leq \left( \frac{1}{K} \sum_{k=1}^{K} \hat{H}_k(\theta_k)^{-1} \right)^{-1} \|\hat{H}_k(\theta_k)^{-1} (\hat{\phi}_k - \phi^*)\|_2.$$  

(54)

Since $H_k(\theta_k^*)^{-1} \geq \frac{\sigma^2}{\rho_0} I_{P_1 \times P_1}$, by Lemma B.3, the event $\mathcal{H}_K = \{\|\hat{H}_k(\hat{\theta}_k)^{-1} - H_k(\theta_k^*)^{-1}\|_2 \leq \frac{\rho}{2}, k = 1, ..., K\}$ implies $\|\frac{1}{K} \sum_{k=1}^{K} \hat{H}_k(\hat{\theta}_k)^{-1} - (1 - \frac{\rho}{2}) \sum_{k=1}^{K} H_k(\theta_k^*)^{-1}\|_2 \leq \frac{\rho}{2}$. Using Lemma B.3 again with $H_k(\theta_k^*) \succeq c I_{P_1 \times P_1}$ as assumed in Assumption 7 the event $\mathcal{H}_K = \{\|\hat{H}_k(\hat{\theta}_k) - H_k(\theta_k^*)\|_2 \leq \frac{\rho}{2}, k = 1, ..., K\}$ implies $\|\hat{H}_k(\hat{\theta}_k)^{-1} - H_k(\theta_k^*)^{-1}\|_2 \leq \frac{\rho}{2}$. Using Lemma B.3 again with $H_k(\theta_k^*) \succeq c I_{P_1 \times P_1}$ as assumed in Assumption 7 the event $\mathcal{H}_K = \{\|\hat{H}_k(\hat{\theta}_k) - H_k(\theta_k^*)\|_2 \leq \epsilon_H, k = 1, ..., K\}$.

Now for any $\epsilon > 0$, define $\epsilon_H = \min\{\epsilon, c\}/4$, then under the event

$$\mathcal{H}_K = \{\|\hat{H}_k(\hat{\theta}_k) - H_k(\theta_k^*)\|_2 \leq \epsilon_H, k = 1, ..., K\}$$  

(55)
we have $\{1/K \sum_{k=1}^{K} \hat{\mathcal{H}}_{k}(\hat{\theta}_{k})^{-1} \}^{-1} - \{1/K \sum_{k=1}^{K} H_{k}(\theta^{*}_{k})^{-1} \}^{-1} \leq \epsilon$. Now using the boundedness of $\|\hat{\phi}^{WD} - \phi^{*}\|$, we have

$$E \left( \|\hat{\phi}^{WD} - \phi^{*}\|_{2}^{2} \right) \leq C_{1} E \left( \|1/K \sum_{k=1}^{K} \hat{\mathcal{H}}_{k}(\hat{\theta}_{k})^{-1}(\hat{\phi}_{k} - \phi^{*})\|_{2}^{2} I(\mathcal{H}^{c}_{K}) \right) + C_{2} E \left( \|1/K \sum_{k=1}^{K} (\hat{\phi}_{k} - \phi^{*}_{k})\|_{2}^{2} I(\Phi \not\in \hat{\mathcal{H}}^{c}_{K}) \right) + C_{3} P(\mathcal{H}^{c}_{K}) \cdot (56)$$

Thus we only need to separately bound the three terms on the RHS of (56). Let us first consider bounding $P(\mathcal{H}^{c}_{K})$. Denote

$$\hat{L}_{k}(\theta_{k}) = \nabla_{\theta}^{2} M_{n,k}(\theta_{k}), \quad L_{k}(\theta_{k}) = \nabla_{\theta}^{2} M_{k}(\theta_{k}),$$

$$\hat{V}_{k}(\theta_{k}) = \hat{L}_{k}(\theta_{k})^{-1} \hat{\Sigma}_{S,k}(\theta_{k}) \hat{L}_{k}(\theta_{k})^{-1} \quad \text{and} \quad V_{k}(\theta_{k}) = L_{k}(\theta_{k})^{-1} \Sigma_{S,k}(\theta_{k}) L_{k}(\theta_{k})^{-1}.$$

By definition of $\hat{\mathcal{H}}_{k}(\theta_{k})$ and the triangle’s inequality, we have

$$\|\hat{\mathcal{H}}_{k}(\hat{\theta}_{k}) - H_{k}(\theta_{k}^{*})\|_{2} \leq \|\hat{V}_{k}(\hat{\theta}_{k}) - \hat{V}_{k}(\theta_{k}^{*})\|_{2} + \|\hat{V}_{k}(\theta_{k}^{*}) - V_{k}(\theta_{k}^{*})\|_{2}. \quad (57)$$

Hence, we can bound those two terms on the RHS of (57) separately. Note that

$$\|\hat{V}_{k}(\hat{\theta}_{k}) - V_{k}(\hat{\theta}_{k})\|_{2} = \|\hat{L}_{k}(\theta_{k})^{-1} \hat{\Sigma}_{S,k}(\theta_{k}) \hat{L}_{k}(\theta_{k})^{-1} - L_{k}(\theta_{k})^{-1} \Sigma_{S,k}(\theta_{k}) L_{k}(\theta_{k})^{-1}\|_{2} \leq 2(\|\hat{L}_{k}(\theta_{k})^{-1} - L_{k}(\theta_{k})^{-1}\|_{2}^{2} + \|L_{k}(\theta_{k})^{-1}\|_{2}^{2}) \|\Sigma_{S,k}(\theta_{k})\|_{2} \quad (58)$$

$$+ (\|\hat{L}_{k}(\theta_{k})^{-1} - L_{k}(\theta_{k})^{-1}\|_{2}^{2} + 2\|L_{k}(\theta_{k})^{-1}\|_{2}^{2}) \|\Sigma_{S,k}(\theta_{k})\|_{2} \|\hat{L}_{k}(\theta_{k})^{-1} - L_{k}(\theta_{k})^{-1}\|_{2}$$

Then, under the event $\mathcal{L}^{c}_{K} = \{\|\hat{L}_{k}(\theta_{k}^{*}) - L_{k}(\theta_{k})\|_{2} \leq \min\{\epsilon \rho_{-}^{2}/2, \rho_{-}/2\}, k = 1, \ldots, K\}$ with $\rho_{-}$ being the lower bound of the eigenvalues of $L_{k}(\theta_{k}^{*})$ as assumed in Assumption 4, we have

$$\|\hat{V}_{k}(\hat{\theta}_{k}) - V_{k}(\hat{\theta}_{k})\|_{2} \leq 2(\epsilon^{2} + \frac{1}{\rho_{-}^{2}}) \|\hat{\Sigma}_{S,k}(\theta_{k})^{-1} - \Sigma_{S,k}(\theta_{k})\|_{2} + (\epsilon^{2} + \frac{2}{\rho_{-}}) \|\hat{L}_{k}(\theta_{k})^{-1} - L_{k}(\theta_{k})\|_{2}, k = 1, \ldots, K. \quad (59)$$

Similar to (58), we have

$$\|\hat{V}_{k}(\hat{\theta}_{k}) - V_{k}(\hat{\theta}_{k})\|_{2} \leq 2(\|\hat{\Sigma}_{S,k}(\theta_{k})^{-1} - \Sigma_{S,k}(\theta_{k})\|_{2} + \|\hat{L}_{k}(\theta_{k})^{-1}\|_{2}^{2} + \|\hat{L}_{k}(\theta_{k})^{-1}\|_{2}) \|\Sigma_{S,k}(\theta_{k})\|_{2} \|\hat{L}_{k}(\theta_{k})^{-1} - L_{k}(\theta_{k})^{-1}\|_{2} \quad (58)$$

Define an event

$$\mathcal{M}_{K} = \left\{\|\hat{L}_{k}(\theta_{k})^{-1}\|_{2} \leq \frac{2}{\rho_{-}} \|\hat{\Sigma}_{S,k}(\theta_{k})\|_{2} \leq 2\rho_{-}, \|\hat{L}_{k}(\theta_{k})^{-1}\|_{2} \leq \min\{\frac{\rho_{-}}{2}, \frac{\epsilon \rho_{-}^{2}}{8}\}, k = 1, \ldots, K\right\}.$$
Under this event, we have for all $k = 1, 2, \ldots, K$,

$$
\| \hat{\nu}_k(\hat{\theta}_k) - \nu_k(\theta^*_k) \|_2 \\
\leq 2(\epsilon^2 + \frac{4}{\rho_-}) \| \hat{\Sigma}_{S,k}(\hat{\theta}_k) - \Sigma_{S,k}(\theta^*_k) \|_2 + (\epsilon + \frac{4}{\rho_-}) \rho_\sigma \| \hat{L}_k(\hat{\theta}_k) - L_k(\theta^*_k) \|_2 \\
\leq (C_1 B_{n,k} + C_2 G_{n,k}) \| \hat{\theta}_k - \theta^*_k \|_2,
$$

(60)

where $B_{n,k} = (1/n) \sum_{i=1}^n B(X_{k,i})$ and $G_{n,k} = (1/n) \sum_{i=1}^n G(X_{k,i})$. Note that $\| \hat{L}_k(\theta^*_k)^{-1} \|_2 \leq \frac{\rho_\sigma}{\rho_-}$ and $\| \hat{\Sigma}_{S,k}(\theta^*_k) \| \leq 2\rho_\sigma$ are implied by $\| \hat{L}_k(\theta^*_k) - L_k(\theta^*_k) \|_2 \leq \frac{\rho_\sigma}{2}$ and $\| \hat{\Sigma}_{S,k}(\theta^*_k) - \Sigma_{S,k}(\theta^*_k) \|_2 \leq \frac{\rho_\sigma}{2}$, respectively. Thus, we define the event

$$
\mathcal{U}_K = \left\{ B_{n,k} \leq 2B, G_{n,k} \leq 2G, \| \hat{L}_k(\theta^*_k) - L_k(\theta^*_k) \|_2 \leq C_1, \right. \\
\left. \| \hat{\Sigma}_{S,k}(\theta^*_k) - \Sigma_{S,k}(\theta^*_k) \|_2 \leq C_2, k = 1, 2, \ldots, K \right\},
$$

which satisfies $\mathcal{U}_K \subset \mathcal{M}_K \cap \mathcal{L}_K$. Under $\mathcal{U}_K$, we have $\| \hat{H}_k(\hat{\theta}_k) - H_k(\theta^*_k) \|_2 \leq C \| \hat{\theta}_k - \theta^*_k \|_2 + \frac{\epsilon_H}{2C}$. Furthermore, we define the following event

$$
\mathcal{A}_K = \mathcal{U}_K \cap (\cap_{k=1}^K \mathcal{E}_k) \cap \{ \| \hat{\theta}_k - \theta^*_k \|_2 \leq \frac{\epsilon_H}{2C}, k = 1, 2, \ldots, K \}.
$$

(61)

By Lemma 6 in Zhang et al. (2013), under the event $\cap_{k=1}^K \mathcal{E}_k$, the event $\{ \| \hat{\theta}_k - \theta^*_k \|_2 \leq \epsilon_H/(2C), k = 1, 2, \ldots, K \}$ is implied by the event $\{ \| \nabla_{\theta_k} M_{n,k}(\theta^*_k) \|_2 \leq (1 - \rho_-)\epsilon_H/(4C), k = 1, 2, \ldots, K \}$. Thus, the event $\mathcal{A}_k$ can be equivalently expressed as

$$
\mathcal{A}_K = \left\{ B_{n,k} \leq 2B, G_{n,k} \leq 2G, \| \hat{L}_k(\theta^*_k) - L_k(\theta^*_k) \|_2 \leq C_1, \right. \\
\left. \| \hat{\Sigma}_{S,k}(\theta^*_k) - \Sigma_{S,k}(\theta^*_k) \|_2 \leq C_2, \| \nabla_{\theta_k} M_{n,k}(\theta^*_k) \|_2 \leq C_3, k = 1, 2, \ldots, K \right\}.
$$

Now with the union bound and Lemma 7 in Zhang et al. (2013), we can obtain that

$$
P((\mathcal{H}_K^c)^c) \\
\leq P(A^c_K) \\
\leq \sum_{k=1}^K \left( P(B_{n,k} \geq 2B) + P(G_{n,k} \geq 2G) + P(\| \hat{L}_k(\theta^*_k) - L_k(\theta^*_k) \|_2 > C_1) \\
+ P(\| \hat{\Sigma}_{S,k}(\theta^*_k) - \Sigma_{S,k}(\theta^*_k) \|_2 > C_2) + P(\| \nabla_{\theta_k} M_{n,k}(\theta^*_k) \|_2 > C_3) \right) \\
\leq CK \left( \frac{1 + L^{2v}}{n^v} + \frac{R^{2v_1}}{n^{v_1}} + \frac{R^{2v_1}}{n^{v_1}} \right) \leq \frac{CK}{n^v},
$$

(62)

where $\bar{v} = \min\{v, \frac{v_1}{2}\}$.

Next we consider bounding $E \left( \frac{1}{K} \sum_{k=1}^K \hat{H}_k(\hat{\theta}_k)^{-1}(\hat{\phi}_k - \phi^*) \right)^2 I(\mathcal{H}_K^c)$ in (56). Recall the definition of $\mathcal{H}_K^c$ in (55), we can naturally decompose the event into $\mathcal{H}_K^c = \bigcap_{k=1}^K \mathcal{H}_K^{c,(k)}$, where
\( \mathcal{H}_K^{e,(k)} = \{ \| \hat{H}_k(\hat{\theta}_k) - H_k(\theta_k^*) \|_2 \leq \epsilon_H \} \). It is noted that for each \( k \), under the event \( \mathcal{H}_K^{e,(k)} \), we have
\[
\| \hat{H}_k(\hat{\theta}_k)^{-1} \|_2 \leq \frac{2}{C^2} \| \hat{H}_k(\hat{\theta}_k) - H_k(\theta_k^*) \|_2 + \| H_k(\theta_k^*)^{-1} \|_2 \leq C.
\]
Since elements of \( \{ \hat{H}_k(\hat{\theta}_k)^{-1}(\hat{\phi}_k - \phi^*)I(\mathcal{H}_K^{e,(k)}) \}_{k=1}^K \) are independent with one another, we decompose the term as follows:
\[
E \left( \frac{1}{K} \sum_{k=1}^K \hat{H}_k(\hat{\theta}_k)^{-1}(\hat{\phi}_k - \phi^*) \| I(\mathcal{H}_K^{e,(k)}) \|_2^2 \right) \leq \max_{1 \leq k \leq K} \left( \frac{C}{K} E \left( \| \hat{\phi}_k - \phi^* \|_2^2 \right) + E \left( \| \hat{H}_k(\hat{\theta}_k)^{-1}(\hat{\phi}_k - \phi^*)I(\mathcal{H}_K^{e,(k)}) \|_2^2 \right) \right). \tag{63}
\]

The first term in the RHS of (63) can be bounded using Lemma B.2. For the second term, we have
\[
E \left( \| \hat{H}_k(\hat{\theta}_k)^{-1}(\hat{\phi}_k - \phi^*)I(\mathcal{H}_K^{e,(k)}) \|_2^2 \right) \leq 2 \| E \left( (\hat{H}_k(\hat{\theta}_k)^{-1} - H_k(\theta_k^*)^{-1})(\hat{\phi}_k - \phi^*)I(\mathcal{H}_K^{e,(k)}) \right) \|_2^2 + 2 \| E \left( H_k(\theta_k^*)^{-1}(\hat{\phi}_k - \phi^*)I(\mathcal{H}_K^{e,(k)}) \right) \|_2^2 \leq C_1 E \left( \| \hat{S}_k(\hat{\theta}_k) - S_k(\theta_k^*) \|_2^2 + \| \hat{L}_k(\theta_k^*) - L_k(\theta_k^*) \|_2^2 + \| \nabla_{\theta_k} M_{n,k}(\theta_k^*) \|_2^2 \right) + C_2 P \left( (A_K^{(k)})^c \right). \]

Using (57), (59) and (60), and decomposing \( A_K \) into \( \cap_{k=1}^K A_K^{(k)} \), we can show by Hölder’s inequality that
\[
E \left( \| \hat{H}_k(\hat{\theta}_k)^{-1} - H_k(\theta_k^*)^{-1} \|_2^2 I(\mathcal{H}_K^{e,(k)}) \|_2^2 \right) \leq C_1 \left( \frac{R^8 + R^4 + L^4}{n^2} + P \left( (A_K^{(k)})^c \right) \right).
\]

Besides, we have that
\[
\| E \left( (\hat{\phi}_k - \phi^*)I(\mathcal{H}_K^{e,(k)}) \right) \|_2^2 \leq 2 \| E(\hat{\phi}_k - \phi^*) \|_2^2 + 2 \| E \left( (\hat{\phi}_k - \phi^*)(1 - I(\mathcal{H}_K^{e,(k)}) \right) \|_2^2.
\]

The second term can be bounded by also conditioning on the event \( A_K^{(k)} \), using the inequality (35) and the Hölder’s inequality, and we will obtain
\[
\| E \left( (\hat{\phi}_k - \phi^*)(1 - I(\mathcal{H}_K^{e,(k)}) \right) \|_2^2 \leq C \left( E \left( \| \nabla_{\theta_k} M_{n,k}(\theta_k^*) \|_2^2 I(\mathcal{H}_K^{e,(k)}) \right) + P \left( (A_K^{(k)})^c \right) \right) \leq C \left( \frac{R^2}{n} \sqrt{P \left( (A_K^{(k)})^c \right) + P \left( (A_K^{(k)})^c \right) } \right) \leq C \left( \frac{R^4}{n^2} + P \left( (A_K^{(k)})^c \right) \right).
\]

And for the first term in the RHS, the following holds from the proof of Theorem 1 of Zhang et al. (2013):

\[ \|E(\hat{\phi}_k - \phi^*)\|_2^2 \leq C \left( \frac{L^2 + R^2G^2}{n^2} + \frac{1}{n^3} \right) \]  

(64)

In summary, we have that

\[ E \left( \frac{1}{K} \sum_{k=1}^{K} \hat{H}_k(\hat{\theta}_k)^{-1}(\hat{\phi}_k - \phi^*)_2^2 I(\mathcal{H}^c_K) \right) \leq C \left( \frac{1 + L^2 + R^2}{nK} + \frac{(L^2 + L^4) + R^2(R^2 + R^6 + G^2)}{n^2} + \frac{1}{n^3} + P(\mathcal{A}_K^{(k)}) \right). \]  

(65)

It remains to bound \( E \left( \frac{1}{K} \sum_{k=1}^{K} (\hat{\phi}_k - \phi^*)_2 I(\hat{\phi} \notin \Phi) \right). \) First we have that

\[ E \left( \frac{1}{K} \sum_{k=1}^{K} (\hat{\phi}_k - \phi^*)_2 I(\hat{\phi} \notin \Phi) \right) \leq \frac{1}{K} \sum_{k=1}^{K} E \left( \|\hat{\phi}_k - \phi^*\|_2 I(\hat{\phi} \notin \Phi) \right). \]

Then, it is noted by (54) that under the event \( \mathcal{H}^c_K, \) the event \( \{\hat{\phi} \notin \Phi\} \) is equivalent to the event \( \{\|\frac{1}{K} \sum_{k=1}^{K} \hat{H}_k(\hat{\theta}_k)^{-1}(\hat{\phi}_k - \phi^*)\|_2 > C\}, \) namely we have that

\[ \{\hat{\phi} \notin \Phi\} \subset \{\|\frac{1}{K} \sum_{k=1}^{K} \hat{H}_k(\hat{\theta}_k)^{-1}(\hat{\phi}_k - \phi^*)\|_2 I(\mathcal{H}^c_K) > C\} \cup (\mathcal{H}^c_K)^c, \]

then we can repeat the conditioning on \( \mathcal{A}_K^{(k)} \) argument to obtain

\[ E \left( \|\hat{\phi}_k - \phi^*\|_2 I(\hat{\phi} \notin \Phi) \right) \leq C \left( \frac{R^4}{n^2} + P(\hat{\phi} \notin \Phi) + P(\mathcal{A}_K^{(k)}) \right). \]

Finally, gathering all the above results, we obtain that

\[ E \left( \|\hat{\phi}^{WD} - \phi^*\|_2^2 \right) \leq C_1 \frac{R^2}{nK} + C_2 \left( \frac{L^2 + L^4}{n^2} + \frac{R^2(R^2 + R^6 + G^2)}{n^2} + \frac{1 + L^{2\nu}}{n^\nu} + \frac{R^{2\nu_1}}{n^{\nu_1}} + \frac{R^{2\nu_1}}{n^{\nu_1}} \right). \]

The proof is now complete.

**B.5 Proof of Theorem 4**

**Proof** With the results in Lemma B.4 and Lemma B.5 the proof follows from a direct application of the Slutsky’s lemma.

**B.6 Proof of Theorem 5**

**Proof** Recall the definition of the event \( \mathcal{H}^c_K \) defined in (55) in the proof of Theorem 3, we can similarly define \( \mathcal{H}^c_{K,j} \) to control the estimation error of \( \{\hat{H}_{k,j}(\hat{\theta}_{k,j})\}_{k=1}^{K}, j = 1, 2. \) Since

\[ E \left( \|\hat{\phi}^{WD}_j - \phi^*\|_2^2 \right) \leq \frac{1}{2} \sum_{j=1}^{2} E \left( \|\hat{\phi}^{WD}_j - \phi^*\|_2^2 \right) = E \left( \|\hat{\phi}^{WD}_1 - \phi^*\|_2^2 \right) \]
it suffices to bound the last term. Under the event $\mathcal{H}_{K,1}^c$ and using boundedness of $\|\hat{\phi}_1^{dWD} - \phi^*\|_2$,

$$E \left( \|\hat{\phi}_1^{dWD} - \phi^*\|_2^2 \right)$$

$$\leq C_1 E \left( \| \frac{1}{K} \sum_{k=1}^{K} \hat{H}_{k,1}(\hat{\theta}_{k,1})^{-1}(\hat{\phi}_{k,2}^{bc} - \phi^*) \|_2^2 I(\mathcal{H}_K^c) \right) + C_2 E \left( \| \frac{1}{K} \sum_{k=1}^{K} (\hat{\phi}_{k,2}^{bc} - \phi^*) \|_2^2 I(\hat{\phi}_1 \notin \Phi) \right)$$

$$+ C_3 P \left( (\mathcal{H}_K^c)^c \right)$$

$$:= C_1 E \left( R_1 \right) + C_2 E \left( R_2 \right) + C_3 P \left( (\mathcal{H}_K^c)^c \right),$$

(66)

which is similar to (56). We have derived the upper bound for in $C_3 P \left( (\mathcal{H}_K^c)^c \right)$ in (62), and it remains to control $R_1$ and $R_2$. Considering $R_1$, we have that

$$R_1 \leq C_1 \left\| \frac{1}{K} \sum_{k=1}^{K} \hat{H}_{k,1}(\hat{\theta}_{k,1})(\hat{\phi}_{k,2} - \phi_k^*) - \frac{1}{n/2} B_k(\theta_k^*) \|_2^2 I(\mathcal{H}_K^c) \right\|$$

$$:= R_1^{(1)}$$

$$+ \frac{1}{n^2} C_2 \sum_{k=1}^{K} \| \hat{B}_{k,2}(\hat{\theta}_{k,2}) I(\mathcal{H}_K^c) (\hat{\phi}_{k,2} - \phi_k^*) \|_2^2 I(\hat{\phi}_{k,2} \in \Theta_k),$$

where $\hat{H}_{k,1}(\hat{\theta}_{k,1}) = (\hat{H}_{k,1}(\hat{\theta}_{k,1})^{-1} - 0)$. Due to Lemma B.7, it remains to control the $R_1^{(1)}$ term. We can decompose the event $\mathcal{H}_K^c$ as $\mathcal{H}_K = \bigcap_{k=1}^{K} \mathcal{H}_k^{(k),\epsilon}$ where $\mathcal{H}_k^{(k),\epsilon} = \{ \| \hat{H}_{k,1}(\hat{\theta}_{k,1}) - H_k(\theta_k^*) \|_2 \leq \epsilon_H \}$. Then, we have

$$R_1^{(1)} \leq \| \frac{1}{K} \sum_{k=1}^{K} \hat{H}_{k,1}(\hat{\theta}_{k,1}) I(\mathcal{H}_k^{(k),\epsilon})(\hat{\phi}_{k,2} - \phi_k^*) - \frac{1}{n/2} B_k(\theta_k^*) \|_2^2.$$

Since $\{ \hat{H}_{k,1}(\hat{\theta}_{k,1}) I(\mathcal{H}_k^{(k),\epsilon}) \}_{k=1}^{K}$ are independent of $\{ \hat{\theta}_{k,2} \}_{k=1}^{K}$ and bounded, $E \left( R_1^{(1)} \right)$ has a similar upper bound as that of Lemma B.8. The $E \left( R_2 \right)$ term is of higher-order and its upper bound can be easily derived. Collecting all the above results, we have the following upper bound

$$E \left( \|\hat{\phi}_1^{dWD} - \phi^*\|_2^2 \right)$$

$$\leq C_1 \frac{R^2}{nK} + C_2 \frac{R^2(L^2 + R^2)}{n^2 K} + C_3 \frac{G^2 R^2 (G^2 + R^2 + G^4)}{n^3} + A^2 R^6 + C_4 \frac{C_B}{n^3}$$

$$+ C_5 K \left( \frac{1}{n^6} + \frac{R^{2\nu_1}}{n^{\frac{3}{2}}} + \frac{R^{2\nu_1}}{n^{\nu_1}} \right),$$

where $C_B$ is the constant term over $n$ appeared in (46). This completes the proof. 

\[\text{B.7 Proof of Theorem 6}\]

\textbf{Proof} Similar to Lemma B.5, we first prove that the following term is of $o_p(\epsilon_H)$:

$$R_H := \{ \sum_{s=1}^{K} \hat{H}_{s,1}(\hat{\theta}_{s,1})^{-1} \}^{-1} \sum_{k=1}^{K} \hat{H}_{k,1}(\hat{\theta}_{k,1})^{-1} (\hat{\phi}_{k,2}^{bc} - \phi^*) - \{ \sum_{s=1}^{K} H_s(\theta_s^*)^{-1} \}^{-1} \sum_{k=1}^{K} H_k(\theta_k^*)^{-1} (\hat{\phi}_{k,2}^{bc} - \phi^*)$$

47
for $K = o(n^2)$. Note
\[
\sqrt{N} \| R_H \|_2 I(\mathcal{H}_{K,1}^c) \\
\leq \sqrt{N} \| \{ \frac{1}{K} \sum_{s=1}^{K} \hat{H}_{s,1}(\hat{\theta}_{s,1})^{-1} \}^{-1} - \{ \frac{1}{K} \sum_{s=1}^{K} H_s(\theta_s^*)^{-1} \}^{-1} \|_2 I(\mathcal{H}_{K,1}^c) \| \frac{1}{K} \sum_{k=1}^{K} \hat{H}_{k,1}(\hat{\theta}_{k,1})^{-1}(\hat{\phi}_{k,2}^{bc} - \phi^*)\|_2 \\
+ C\sqrt{N} \| \frac{1}{K} \sum_{k=1}^{K} (\hat{H}_{k,1}(\hat{\theta}_{k,1})^{-1} - H_k(\theta_k^*)^{-1})(\hat{\phi}_{k,2}^{bc} - \phi^*)\|_2 I(\mathcal{H}_{K,1}^c) \\
:= R_{H,1} + CR_{H,2}
\]
For $K = o(n^2)$, we have shown in the proof of Theorem 5 that
\[
I(\mathcal{H}_{K,1}^c)\| \frac{1}{K} \sum_{k=1}^{K} \hat{H}_{k,1}(\hat{\theta}_{k,1})^{-1}(\hat{\phi}_{k,2}^{bc} - \phi^*)\|_2 = O_p(\frac{1}{\sqrt{N}}).
\]
Besides, we also have that
\[
\| \{ \frac{1}{K} \sum_{s=1}^{K} \hat{H}_{s,1}(\hat{\theta}_{s,1})^{-1} \}^{-1} - \{ \frac{1}{K} \sum_{s=1}^{K} H_s(\theta_s^*)^{-1} \}^{-1} \|_2 I(\mathcal{H}_{K,1}^c) = O_p(\frac{1}{\sqrt{N}}).
\]
Combining those two results we prove that $R_{H,1} = O_p(\frac{1}{\sqrt{N}}) = o_p(1)$. Considering $R_{H,2}$, we have
\[
R_{H,2} \leq \sqrt{N} \| \frac{1}{K} \sum_{k=1}^{K} (\hat{H}_{k,1}(\hat{\theta}_{k,1}) - \hat{H}_{k,1}(\theta_k^*))I(\mathcal{H}_{K,1}^{(k),c})(\hat{\phi}_{k,2}^{bc} - \theta_k^*)\|_2 := R_{H,2}^{(1)}
\]
From previous derivations, we know that when $K = o(n^2)$ the leading order term in $R_{H,2}^{(1)}$ is
\[
R_{H,2}^{(2)} = \sqrt{N} \| \frac{1}{K} \sum_{k=1}^{K} (\hat{H}_{k,1}(\hat{\theta}_{k,1}) - \hat{H}_{k,1}(\theta_k^*))I(\mathcal{H}_{K,1}^{(k),c}) \frac{1}{n/2} \sum_{i=1}^{n/2} d_i(2)(\theta_k^*)\|_2,
\]
where $d_i(\theta_k^*) = Q_{k}(\theta_k^*)\nabla_{\theta_k} M(X_{k,i}, \theta_k^*)$. So we only need to show that $R_{H,2}^{(2)} = o_p(1)$. Denote $m = n/2$, then using the independence between $\hat{H}_{k,1}(\hat{\theta}_{k,1})$ and $d_i(2)(\theta_k^*)$, we have that
\[
E(R_{H,2}^{(2)})^2 \leq \frac{N}{K^2} \sum_{k=1}^{K} E \left( \| (\hat{H}_{k,1}(\hat{\theta}_{k,1}) - \hat{H}_{k,1}(\theta_k^*))I(\mathcal{H}_{K,1}^{(k),c}) \|_2^2 \right) E \left( \frac{1}{m} \sum_{i=1}^{m} d_i(2)(\theta_k^*)\|_2^2 \right) = O(\frac{1}{n}).
\]
Then by Markov’s inequality it’s direct to show $R_{H,2}^{(2)} = o_p(1)$. Now with Slutsky’s lemma, it remains to establish the asymptotic normality of
\[
\frac{1}{2} \sum_{j=1}^{2} \sum_{s=1}^{K} H_s(\theta_s^*)^{-1} - \sum_{k=1}^{K} H_k(\theta_k^*)^{-1} \hat{\phi}_{k,j}^{bc},
\]
and the proof directly follows from the proof of Lemmas B.7 and B.9.
B.8 Proof of Theorem 7 and Corollary 8

Proof The proof can be easily derived based on previous derivations.

B.9 Proof of Theorem 9

Proof To apply Theorem 1 in Yuan and Jennrich (2000), we need to check the uniform convergence of 
\[
\frac{1}{n}\sum_{i=1}^{n} \left( \psi_{\theta}^T(X_{k,i}; \theta_k)^T \psi_{\theta}^T(X_{k,i}; \theta_k) \right)^T.
\]
This is actually the last \(p_2\) columns of \(\nabla_{\theta_k}^2 M_{n,k}(\theta_k)\) for \(\theta_k \in U_k\), so we only need to show the uniform convergence of \(\nabla_{\theta_k}^2 M_{n,k}(\theta_k)\) in \(U_k\). By Assumption 5, \(\nabla_{\theta_k}^2 M(x; \theta_k)\) is Lipschitz continuous w.r.t. \(\theta_k\) for \(\theta_k \in U_k\), then we can directly apply Corollary 3.1 of Newey (1991) to establish the required uniform convergence.

Now we are to show \(\hat{\lambda}_k^{(2)} \xrightarrow{P} \lambda_k^*\). Following the proof of Lemma 6 in Zhang et al. (2013), we can first show that under the event \(E_{W,k}\), \(M_{n,k}(\theta_k)\) is \((1 - \rho)\rho_\rightarrow\)-strongly convex on the ball \(\bar{U}_k = \{\|\theta_k - \theta_k^*\|_2 \leq \rho_k\}\), where \(\rho_k \leq \min\{\frac{\rho_\rightarrow}{\rho_\rightarrow}, \rho\}\). Define the event \(E_{W,D,k} = \{\|\phi_{WD} - \phi^*_k\|_2 < \frac{\rho_k}{2}\}\), then under this event, \(\hat{\theta}_k^* = (\hat{\phi}_{WD}, \lambda_k^*) \in \bar{U}_k\). For any \(\hat{\theta}_k' = (\hat{\phi}_{WD}, \lambda_k') \in \Theta_k\), if \(\hat{\theta}_k' \notin \bar{U}_k\), then under \(E_{W,D,k}\), there exists \(w_0 \in [0,1]\) such that \(\theta_k' = w_0\theta_k^* + (1 - w_0)\hat{\theta}_k^*\) lies on the surface of the ball \(\bar{U}_k\), and thus \(\|\theta_k' - \hat{\theta}_k^*\|_2 = w_0\|\theta_k^* - \hat{\theta}_k^*\|_2 \in (0, \frac{3\rho_k}{2})\). Now under \(E_{W,D,k}\) we have that

\[
M_{n,k}(\theta_k') \geq M_{n,k}(\theta_k^*) + \langle \nabla_{\theta_k} M_{n,k}(\theta_k^*), \theta_k' - \theta_k^* \rangle \\
\geq M_{n,k}(\hat{\theta}_k^*) + \langle \nabla_{\theta_k} M_{n,k}(\hat{\theta}_k^*), \theta_k' - \hat{\theta}_k^* \rangle + \frac{1}{2}(1 - \rho)\rho_\rightarrow \frac{\rho_k^2}{4},
\]

where the first inequality holds due to the convexity of \(M_{n,k}(\theta_k)\) on \(\bar{U}_k\) and the second holds due to the strong convexity on \(\bar{U}_k\). The last inequality holds due to \(\theta_k' - \hat{\theta}_k^* = \frac{1 - w_0}{w_0}(\hat{\theta}_k, \lambda_k')\). When \(\hat{\theta}_k' \in \bar{U}_k\), with strong convexity Equation (67) still holds with \(\frac{\rho_k^2}{4}\) changed to \(\|\lambda_k - \lambda_k^*\|_2^2\).

In any case the following relationship holds under the event \(E_{W,D,k}\):

\[
M_{n,k}(\theta_k') \geq M_{n,k}(\theta_k^*) + \langle \nabla_{\theta_k} M_{n,k}(\theta_k^*), \theta_k' - \theta_k^* \rangle + \frac{1}{2}(1 - \rho)\rho_\rightarrow \min\{\frac{\rho_k^2}{4}, \|\lambda_k - \lambda_k^*\|_2^2\}.
\]

Rewriting the inequality we obtain that

\[
\min\{\|\lambda_k - \lambda_k^*\|_2, \frac{\rho_k^2}{4}\} \leq \frac{2}{(1 - \rho)\rho_\rightarrow} \left( M_{n,k}(\theta_k') - M_{n,k}(\theta_k^*) + \langle \nabla_{\theta_k} M_{n,k}(\theta_k^*), \theta_k' - \theta_k^* \rangle \right)
\leq \frac{2}{(1 - \rho)\rho_\rightarrow} \left( M_{n,k}(\theta_k') - M_{n,k}(\theta_k^*) + \|\nabla_{\theta_k} M_{n,k}(\theta_k^*)\|_2\|\theta_k' - \theta_k^*\|_2 \right).
\]

(68)

Now if we denote \(\theta_k^{(2)} = (\phi_{WD}, \hat{\lambda}_k^{(2)})\) and set \(\theta_k' = \kappa\theta_k^{(2)} + (1 - \kappa)\hat{\theta}_k^*\) for any fixed \(\kappa \in [0,1]\), we will have

\[
\min\{\kappa\|\hat{\lambda}_k^{(2)} - \hat{\lambda}_k^*\|_2, \frac{\rho_k^2}{4\kappa\|\hat{\lambda}_k^{(2)} - \hat{\lambda}_k^*\|_2}\} \leq \frac{2(\kappa\theta_k^{(2)} + (1 - \kappa)\hat{\theta}_k^* - M_{n,k}(\hat{\theta}_k^*))}{\kappa(1 - \rho)\rho_\rightarrow} + \frac{2\|\nabla_{\theta_k} M_{n,k}(\hat{\theta}_k^*)\|_2}{(1 - \rho)\rho_\rightarrow}.
\]

49
By definition we have $M_{n,k}(\theta_{1,k}^*) \leq M_{n,k}(\hat{\theta}_k^*)$ and thus by convexity we have

$$\min \{ \kappa \lambda_k^{(2)} - \lambda_k^* \| 2, \frac{\rho_k^2}{4\kappa \lambda_k^{(2)} - \lambda_k^*} \} \leq \frac{2\| \nabla \theta_k M_{n,k}(\hat{\theta}_k^*) \|_2}{(1 - \rho) \rho_-}.$$ 

Define the event $E_{s,k} = \{ \frac{2\| \nabla \theta_k M_{n,k}(\hat{\theta}_k^*) \|_2}{(1 - \rho) \rho_-} \leq \frac{\rho_k}{2} \}$, then under this event we have

$$\min \{ \kappa \lambda_k^{(2)} - \lambda_k^* \| 2, \frac{\rho_k^2}{4\kappa \lambda_k^{(2)} - \lambda_k^*} \} \leq \frac{\rho_k}{2}.$$ 

If $\| \lambda_k^{(2)} - \lambda_k^* \|_2 > \frac{\rho_k}{2}$, we can set $\kappa = \frac{\rho_k}{2\| \lambda_k^{(2)} - \lambda_k^* \|_2}$, which leads to a contradiction. Thus we have $\| \lambda_k^{(2)} - \lambda_k^* \|_2 \leq \frac{\rho_k}{2}$. Then using Equation (68) we have

$$\| \lambda_k^{(2)} - \lambda_k^* \|_2 \leq \frac{2\| \nabla \theta_k M_{n,k}(\hat{\theta}_k^*) \|_2}{(1 - \rho) \rho_-}.$$ 

Since $\hat{\theta}_{WD}$ is consistent, we have $P(E_{WD,k}) \rightarrow 1$. Besides, we already know that $P(\mathcal{E}_k) \rightarrow 1$. Due to the form of the event $E_{s,k}$ and inequality (69), it remains to show $\| \nabla \theta_k M_{n,k}(\hat{\theta}_k^*) \|_2 = o_P(1)$ to establish the consistency of $\hat{\lambda}_k^{(2)}$. Note

$$\| \nabla \theta_k M_{n,k}(\hat{\theta}_k^*) \|_2 \leq \| \nabla \theta_k M_{n,k}(\hat{\theta}_k^*) - \nabla \theta_k M_{n,k}(\theta_k^*) \|_2 + \| \nabla \theta_k M_{n,k}(\theta_k^*) \|_2$$

and the latter term is of $O_P(\frac{1}{n^{1/2}})$. Using the consistency of $\hat{\theta}_{WD}$ we can show $\| \nabla \theta_k M_{n,k}(\hat{\theta}_k^*) - \nabla \theta_k M_{n,k}(\theta_k^*) \|_2 = o_P(1)$. Besides, since $\hat{\theta}_{WD}$ is $\sqrt{N}$-consistent and $K \rightarrow \infty$, then $\sqrt{n}(\hat{\theta}_{WD} - \theta^*) = o_P(1)$ and the asymptotic normality of $\sqrt{n}(\frac{1}{n} \sum_{i=1}^n \psi(\lambda(X_{k,i}; \theta_k^*), \lambda_k^*, \alpha_k^*), \theta_k^*)$ is implied by the asymptotic normality of $\sqrt{n}(\frac{1}{n} \sum_{i=1}^n \psi(\lambda(X_{k,i}; \theta_k^*), \lambda_k^*, \alpha_k^*))$ and Slutsky’s lemma. Now we apply Theorem 1 in Yuan and Jennrich (2000) and the result follows.

Appendix C. Additional numerical results

C.1 Simulation results based on the errors in variables model

In this simulation experiment, we simulated the errors-in-variables Model (6) with the objective function (7) to compare the performance of the full sample, the split-and-conquer and the weighted distributed estimators: $\hat{\phi}_{full}$, $\hat{\phi}_{SaC}$ and $\hat{\phi}_{WD}$. The simulation was carried out by first generating IID $\{Z_{i,k}\}$ from $N(\mu_Z, \sigma_Z^2)$, and then upon given a $Z_{i,k}$, $(X_{k,i}, Y_{i,k})^T$ were independently drawn from $N((Z_{i,k}, \phi^* + \lambda_k^* Z_{i,k})^T, \sigma^2 I_{2 \times 2})$. We chose $\phi^* = 1$, $K = 2$, $\sigma = 1$ and $n_1 = n_2 = 5 \times 10^4 = N/2$, and $\lambda_k^*$, $\mu_Z$ and $\sigma_Z^2$ were those reported in Table 4 under four scenarios. As discussed in Section 3, the relative efficiency of $\hat{\phi}_{full}$ to $\hat{\phi}_{SaC}$ depends on the ratio $\sigma^2 (E(Z))^2 / (\text{Var}(Z) E(Z^2))$ as shown in (8). We designed four scenarios according to the above ratio under $\lambda_1^* \neq \lambda_2^*$ and $E(Z) \neq 0$, respectively, which represented the settings where the full sample estimator $\hat{\phi}_{full}$ would be less (Scenario 1) or more (Scenario 2) efficient than the split-and-conquer estimator as predicted by the ratio but not as efficient as the weighted distributed estimator $\hat{\phi}_{WD}$. Scenario 3 ($\lambda_1^* \neq \lambda_2^*, E(Z) = 0$) was the case when $\hat{\phi}_{full}$ and $\hat{\phi}_{WD}$ would be asymptotically equivalent, and both estimators would be more efficient than $\hat{\phi}_{SaC}$. Scenario 4 was the homogeneous case with $\lambda_1^* = \lambda_2^*$. 

---

This text is a continuation from the previous page, discussing the results and methods of the simulation experiment.
in which all three estimators would have the same asymptotic efficiency. For all four scenarios, the ARE column of Table 4 confirmed the relative efficiency as predicted by the asymptotic variances in (8), and was well reflected in the comparison of the root mean squared errors, as the bias is of smaller order as compared with that of the standard deviation and thus negligible.

Table 4: Average root mean squared error (RMSE) and the standard deviation (SD), multiplied by $10^2$, of the full sample estimator $\hat{\phi}_{\text{full}}$, the SaC estimator $\hat{\phi}^{\text{SaC}}$ and the WD estimator $\hat{\phi}^{\text{WD}}$ under four scenarios for the errors-in-variables model (12) for $N = 10^5$, $K = 2$ and $n_1 = n_2$. AREs (asymptotic relative efficiency) of $\hat{\phi}_{\text{full}}$ to $\hat{\phi}^{\text{SaC}}$ are calculated from (8).

C.2 Simulation results based on the logistic model

Figure 3 reports the absolute bias and root mean squared errors of the estimators when $p_2 = 4$. Table 5 reports the empirical coverage and the average width of the CIs when $p_2 = 4$. Table 6 reports the average CPU time per simulation run based on 500 replications of the five estimators for a range of $K$ for the logistic regression model with $p_2 = 4$. It is observed in Figure 3 that the bias of the estimators were smaller with $p_2 = 4$ compared to the results with $p_2 = 10$ in Figure 1. As a consequence, the CIs based on the weighted distributed estimator had adequate coverage probabilities even when $K = 1000$.

C.3 Pre-processing of the real data

The arrival delay of the previous flight that utilized the same plane was obtained by matching the tail number of the plane. The three meteorological factors (rain rate, close surface air pressure, and temperature) were obtained by matching this airline’s on-time performance data with the ERA5 hourly data (https://cds.climate.copernicus.eu/). This dataset includes reanalysis from 1959 onwards whose temporal and spatial resolutions are one hour and $0.25^\circ \times 0.25^\circ$, respectively. We applied the $f(x) = \log(1 + x)$ transformation to the rain variable due to its serious skewness. We also
Figure 3: Average simulated bias (a) and the root mean squared errors (RMSE) (b) of the weighted distributed (WD) (red circle), the split-and-conquer (SaC) (blue triangle), the debiased split-and-conquer (dSaC) (green square), the debiased weighted distributed (dWD) (purple cross), the subsampled average mixture SAVGM (pink square cross) estimators, with respect to the number of data block $K$ for the logistic regression model with the dimension $p_2$ of the nuisance parameter $\lambda_k$ being 4, and the full sample size $N = 2 \times 10^6$.

standardized each covariate in each of the data blocks before performing the logistic regression analysis.

We chose the parameter of the three meteorological factors as the common parameter based on Figure 4, which shows that the local estimates of those three parameters are the most concentrated.
Table 5: Coverage probabilities and widths (in parentheses, multiplied by 100) of the $1 - \alpha$ confidence intervals for the common parameter $\phi$ in the logistic regression model based on the asymptotic normality of the split-and-conquer (SaC), the weighted distributed (WD), the debiased split-and-conquer (dSaC) and the debiased weighted distributed (dWD) estimators with respect to the number of data blocks $K$. The dimension $p_2$ of the nuisance parameter $\lambda_k$ is 4 and total sample size $N = 2 \times 10^6$
